PRACTICAL POINTS IN DIAGNOSIS AND ROUTINE TREATMENT OF PULMONARY TUBERCULOSIS.*

25/2

B

BY PETER W. EDWARDS, M.B. EDIN.,

MEDICAL SUPERINTENDENT, CHESHIRE JOINT SANATORIUM, MARKET DRAYTON, SALOP; AND OF WRENBURY HALL TUBERCULOSIS INDUSTRIAL COLONY, NEAR NANTWICH, CHESHIRE.

IT is a prevalent idea that sanatorium treatment is merely a matter of open air. This may be a true description of some sanatoria; but most medical superintendents are agreed that the drawback to many sanatoria is over-much fresh air and that the alpha and omega of successful treatment is *rest*, properly applied and sedulously controlled.

The following are a few practical points in the diagnosis and treatment of pulmonary tuberculosis and a brief description of the routine at the Cheshire Joint Sanatorium. It is not claimed that this treatment "cures"; but there may be other reasons for poor results.

Delay in Beginning Treatment.

Like cancer and venereal disease pulmonary tuberculosis should be tackled early. Only 14 per cent. of our cases arrive at the sanatorium within three months of the onset of symptoms; a further 21 per cent. come within six months; 19 per cent. within twelve months, and another 22 per cent. within two years. Alas, 24 per cent. do not come until more than two years have elapsed. Our patients are classified according to Turban's classification into Stadium 1 (15·6 per cent.), Stadium 2 (18·2 per cent.), and Stadium 3 (66·1 per cent.)—i.e., two-thirds are advanced cases of pulmonary tuberculosis. Again, four out of five have tubercle bacilli in the sputum on admission.

There is obviously something amiss; but in the presence of such old-standing material it is useless decrying sanatorium routine and its results.

Where is the weakness? We must conclude that somewhere there is a gaping hiatus and this hiatus is the cause of most of the poor results; for the advanced case must once have been early, and early tubercle is curable. Probably there are a number of factors responsible for the hiatus—e.g., the economic position and the prejudice of the lay people, the stressing of prevention as though it were opposed to treatment, the conditions of work and pay of some physicians in the tuberculosis service, the scepticism of the general practitioner, and lastly, and most important, the lack of knowledge.

The lay people are afraid of pulmonary tuberculosis and, unfortunately, not afraid of the causes of pulmonary tuberculosis. Many of them spend their leisure hours in a body-destroying manner and do not indulge in sufficient air, exercise, and rest in their daily life, while their diet, though vastly improved, is still unphysiological. Further, though suspicious of pulmonary tuberculosis, they avoid a physician up to the last moment; for they realise that they will probably be sent away and quite possibly lose their employment. When in the sanatorium they know that their absence from home means less food for their families, and so they cannot afford time to tackle the disease adequately. Some do not realise the nature of the disease, for when weight increases and a sense of fitness returns, they, against all advice, insist upon going home. Again, in other cases the friends see the patient with rosy cheeks, looking better than ever and perhaps doing some gardening, and at once they demand his discharge saying there can be nothing wrong.

This ignorance and the economic position of the laity lead to delay in diagnosis, delay in seeking treatment, refusal of routine treatment, and to a curtailment of the sojourn in the sanatorium.

THE TUBERCULOSIS SERVICE.

It is quite right to stress the preventive aspect of public health work, but it is wrong to ignore and belittle treatment, which at present must be an essential part of a full-orbed public health scheme. The wide outlook is shallow if efficient treatment is not prominent, for imagination and sympathy are still required in public medicine, and though the eye be well practised in nature and great schemes of prevention be adumbrated, let not our minds be bounded and mean.

Sanatorium sites are often badly chosen; hopeless buildings erected; poor equipment purchased and essential equipment despised; a man appointed to the post and adequate assistance refused. He cannot do the work, and so we get merely the semblance of treatment.

The unsatisfactory conditions of service of many tuberculosis officers and medical superintendents is the next cause of failure in our handling of the tuberculous. There are excellent tuberculosis officers with commensurate facilities, and they are specialists of a high rank; but often tuberculosis officers are badly paid and denied laboratory and X ray facilities and even clerical assistance, so that their time is wasted and their keenness is destroyed in filling up endless forms which would be more valuable if filled up by a clerk from competent data made available by the tuberculosis officers whose time should be spent doing consulting work and not in office routine.

What has been said of the tuberculosis officer applies in all particulars to the medical superintendents. Even if they keep up to date in general medicine and in the treatment of pulmonary tuberculosis, whilst they have the consolation of work well done they have often nothing else. Committees too commonly only demand a low figure for running the institution and are contented therewith.

Before dealing with the general practitioner, I will refer to our lack of knowledge, as research is the weakest link. There are innumerable problems in tuberculosis that need solving—e.g., housing conditions are worse than ever; but pulmonary tuberculosis is on the decrease. Is this decrease due to the repeal of the Corn Laws? Is tuberculosis a disease of nutrition? What is adult tuberculosis?—a recrudescense or a reinfection, or perhaps one type is a recrudescense and another type a reinfection. Is pulmonary tuberculosis infectious? What else should be done in prevention? Would the provision of more beds in hospitals, sanatoria, colonies, and perhaps in convalescent homes, be the surest foundation for all anti-tuberculosis work? Research is the great need in prevention and treatment, but in the meantime apply what knowledge we have, shun false doctrine, and have more research.

---

* Paper read before members of the Hyde Division of the British Medical Association on Dec. 9th, 1931.

THE GENERAL PRACTITIONER.

The general practitioner—what of him? He is the backbone of medicine, preventive and clinical. Yet in his training to-day the medical student is divorced from intimate contact with tuberculosis—a deplorable state of affairs. So much time is spent in gaining knowledge of abstruse laboratory tests, which he will never perform; for all that he needs to know is when to call for and how to interpret the results of such tests; and rare medical diseases absorb an unequal proportion of his stay at the bedside. The teaching hospital has few or no beds for so common and serious a disease as pulmonary tuberculosis, and therefore we are not surprised that glaring phthisis, let alone its early manifestations, is not detected. The short course in tuberculosis given at certain centres does not meet the situation.

Some general practitioners are against sanatoria, more are sceptical, a few have a pathetic optimism about the curative power of the sanatorium, and there is a variety of general practitioners, small in number, who has a pathetic faith in an adventurer—especially in the foreigner. This variety will hold public meetings, raise funds, and disturb Parliament for his foreigner's sake. He will ignore, however, the findings of accredited scientists, both British and foreign. He does much harm, and forgets that there are plenty of physicians suffering from pulmonary tuberculosis who work and hope for the day when a real cure will be available. This generation apparently is still an evil and adulterous one, for no sign has been given unto us! The optimistic general practitioner finds an advanced case of pulmonary tuberculosis and insists upon sanatorium treatment, when really a hospital or nursing home would be the better place. Rightly, as I shall show later, the modern sanatorium has become more like a hospital; but it is not for hopeless cases.

The general practitioner who is against a sanatorium and the sceptical general practitioner, have probably been unaware of the type of case sent to the sanatorium and likewise they frequently confuse the issue. It is no argument against the sanatorium that the unfortunate patient must needs return to overcrowded home conditions and poverty. It is merely an argument for better social conditions—conditions probably improved more by political and industrial action than by any other means. Like Christianity, sanatoria have not failed, they have never been given a chance.

May I make this plea to the adversary and the sceptic? Give the sanatorium a chance. Get it built on a proper site; get an expert to advise on the buildings and the equipment, and give the physician who has to run it adequate assistance and finally supply suitable cases.

POINTS IN DIAGNOSIS.

As primarily the diagnosis and care of pulmonary tuberculosis rests with the general practitioner I stress the following points:—

1. Suspect pulmonary tuberculosis if a cough persists more than ten days and pay attention to the history of your patient and the classical symptoms of pulmonary tuberculosis.

2. When you suspect tubercle get, if possible, a positive diagnosis quickly, and should it happen the diagnosis cannot be made, treat the patient as tuberculous so long as you are in doubt.

3. Remember the sputum, temperature, pulse. Seek sputum, have it examined and again seek more sputum and send it up daily; get special methods adopted for examining it. The very earliest lesion may produce tubercle bacilli. A few negative resu may mean little; but do not insist upon a positi sputum before diagnosing pulmonary tuberculos Take the temperature. The temperature in an acu disease is readily and satisfactorily taken in moment or two, but temperature taking in ear phthisis demands time and needs to be tak accurately, whatever method is adopted. I pref rectal temperatures and they are taken with ordinary thermometer. Give the thermometer ti to act, particularly if attempting to obtain an o temperature. Record the temperature before exerci immediately on completion, and after three-quarte of an hour's rest. Take the pulse. Beware of t moderately rapid pulse.

4. Do not place your trust entirely in percussi and auscultation. By all means inspect, palpat percuss, and auscultate; but if the result is negati and the patient is ill, think it possible that yo tactile sense is poor and your hearing defectiv but, still more, realise that even cavities may refu to give signs on physical examination, and cavitie as will be shown on the screen, may *develop* in few months. Remember a recent onset may sho no physical signs and yet mean extensive involveme of lung.

5. Radiograph your patient and insist upon technically satisfactory picture. I do not mainta that the Coolidge tube has ousted Laennec's; but do insist that the chest has not been examined if technically perfect radiogram is not available, and go further and say that the earliest radiologic evidence is found only in good stereographic photographs. The stereo is not a luxury. It giv information earlier than the flat film and, in speci cases, information that can only be obtained by series of flat films.

The diagnosis of pulmonary tuberculosis may re upon symptoms alone, or a suggestive history obtained and tubercle bacilli are found, withou symptoms and without physical signs. Usuall however, before the appearance of tubercle bacil the stereogram reveals the focus, later this foc is seen on the flat film and, unfortunately, it is st later before the old methods of physical examinatio help—i.e., on clinical examination the lesion is n found or appears limited but X ray shows it to more extensive and alas, autopsy reveals it as massive infection.

In a word, pending diagnosis, treat your patient tuberculous, let the history and symptoms be yo main guide, hunt the sputum again and agai take the temperature and pulse, do a thoroug clinical examination repeatedly, and get a goo radiogram.

Management of Patient at Home.

The diagnosis having been made, interest in th patient should be redoubled. To him who believe sanatorium methods useless, I dare not speak; bu upon the sceptic and the optimist, I urge that th patient be put to bed in a room with door and window open, even though the house be small and in a crowde area, put your patient to bed and never mind ho he feels. Keep him in bed and keep him *cool*. Teac him to rest and to scrap most of the bed-clothes, fo you will save valuable time by this method. Earl disease demands absolute rest, and even talking i working and his friends must appreciate this thoug it will be difficult to get this simple remedy adopted Teach that walking about and loafing in the par looking for fresh air is entirely wrong. Instruct i simple hygienic methods and endeavour to see that are carried out. Encourage a wholesome ıd banish faith in excessive quantities of fats. ımend that the length of stay in the sana- . should be at least nine months—the earlier ıse the more important the length of stay. a sharp lookout on all contacts and be glad if negative. Watch the families, since probably st way to escape tuberculosis is by reasonable est, and air. These are methods of treatment, ossibly the best methods of prevention, within mily.

the discharge from the sanatorium the patients different classes. There are those who cannot those who can work under ordinary conditions, hose who should work under sheltered condi- -preferably in a colony similar to Papworth. the "can't works," for they are poles apart the "won't works," and encourage them to the Better if possible to encourage them as their gth fails to seek the shelter of a suitable hospital. ose who can work foster restful and reasonable , countenance work and discourage idling and hem to spend their off-time well. The dangerous are the free hours. I have come to fear six n o'clock at night. These are the risky hours e tuberculous. Cinemas, public houses, churches, ome fire, all should be banned. The home fire ? It is then the atmosphere resembles Central a in humidity and stillness of air; then that ıg gives place to laughter and laughter to ning and its attendant perils. The patients are opardy, so teach the friends this and let the nts, for a couple of years at least, after leaving anatorium, develop a quiet handicraft at these s in the bedroom, under conditions of moving and rest, and thus save themselves from cessary hazards.

me of the women patients, unfortunately, become pregnant. As with marriage, so with nancy, advice is sought and rarely followed. is a serious problem, for it is idle to pretend pregnancy is a normal physiological process r civilised conditions, and the tuberculous nant woman is in grave danger. We all know e who have weathered labour successfully; we know hosts who have become wrecks. commend an early therapeutic abortion; failing a Cæsarean section at term and send the mother k to the sanatorium as soon as possible, since a e in the household means no rest for the mother tuberculous mothers must have rest. Ideally, e should be special sanatoria for pregnant women.

f a slight ailment intervenes—such as a cold— ıt it by strict bed. The tuberculous also are le to all other ills.

The Sanatorium.

ype of case.—Granted that the temperament ight, doubtful, early, acute, and extensive cases uld be sent to the sanatorium; but it is uneconomic l unkind to send very advanced cases.

he aim.—The sanatorium aims, firstly, at educating patient in a correct mode of life and in simple gienic precautions; secondly, at developing in the tient a correct mental attitude towards the disease; d thirdly, at rendering him symptomless, his ıtum negative, and his sedimentation rate normal.

Classification at the end of treatment.—On discharge tients are classified into three groups: Quiescent, nproved, and Worse. Quiescence means the absence symptoms and signs, except those compatible ith a healed [illegible], and that the sputum, if present, has been negative over a period of three months. Patients are not discharged as "arrested" or "cured." The former term is reserved for those who have been quiescent for two years and the latter term for those who remain arrested for a further three years.

Routine.—The first thing is to verify the diagnosis and assess the case. A complete history is obtained, and to help in this important matter the patient fills up a form which serves to stimulate his memory, and this form is given to the medical officer in charge of the case when he comes to take the history. An accurate history is indispensable, and it should be entered fully in chronological order and be a record of which the medical officer is justly proud. The symptoms are likewise entered. Patients are often as unaware of their symptoms as of their history—e.g., cough becomes a habit and dyspnœa tolerable and unnoticed. Therefore, the nurse's help in this sphere is valuable. Respiration, pulse-rate, and temperature are taken every four hours—the temperature per rectum. The sputum is collected and measured. The weight, when stripped, the height, and the blood pressure are taken. The physical examination is comprehensive and naturally takes in all organs, and in order to remember axillæ we have charts of them as well as the usual charts of the thorax. Particular attention should be paid to the orifices—nose, mouth, and ears, and the larynx is always examined.

SPECIAL METHODS OF EXAMINATION.

Radiographic examination consists in screening and in obtaining suitable pictures. Screening, when the eyes are fully accommodated, is a definite gain. It will show movements and give a general idea of all parts of the chest. If little abnormal is seen, a pair of stereophotographs is demanded; if something unusual is seen—e.g., a cyst, a growth, or an aneurysm—photographs in specified planes may be ordered. The radiograms need to be "shot" in such a manner that another one can be taken at any future time, under precisely the same conditions, and therefore, in each case, a record of all constants is kept. An addition or reduction in body-weight will be the only variant and calls for an alteration in kilovolt peak only.

The laboratory.—A sample of *urine* is examined. A specimen of *sputum* is obtained in an ice-cream carton with a press-down lid. This container is cheap and guarantees the absence of tubercle bacilli from contaminants. If the specimen is negative to the usual Ziehl-Neelsen's test on three successive days, a seventy-two hour collection of sputum is obtained for gasolene concentration and if it is still negative an attempt is made to culture the bacilli on special media. The culture method has positive advantages: it is cheaper than guinea-pig inoculation and the result is known in about ten days. Some patients will not produce sputum and an effort is made to obtain this when examining the larynx.

The patient's *blood* is the laboratory's next concern and the rate of sedimentation is estimated. There are different methods, and the one we use is akin to Westergren's. The tubes are always at the same temperature and the readings are made at the end of each hour up to five hours and then after twenty-four hours and the result graphed. I should say here that the sedimentation rate is of high value in prognosis and if all else appears normal and the sedimentation rate is rapid, beware! It is desirable that a Wassermann test be done as a routine. We do a differential blood count on special cases only.

Dental surgeon.—All patients are seen by the dental surgeon who then undertakes any necessary treatment.

The clinic.—During the first fortnight the patient is in bed. By this time the mental attitude of the patient is probably known, for it is futile to ignore the mental side; chronic disease produces a chronic mental outlook and usually the consumptive has not been taught to be a consumptive and to accept life upon the terms upon which it is offered and therefore much is unintelligible to him. At the end of this fortnight the patient is brought to the clinic and all data are checked by the medical superintendent and his colleagues. Usually this means some slight alteration in the history and then the medical officers examine the patient together, and the findings—often composite—are put on the diagrams and these are correlated with the laboratory and X ray findings. After consultation, treatment and if necessary further special methods of investigation are prescribed.

Special tests.—The special method of further investigation may be by exercise, temperatures, tuberculin test, guinea-pig inoculation, blood counts, and by lipiodol—a valuable aid in differential diagnosis. The exercise test guides us as to activity. The tuberculin test, if negative, definitely excludes tuberculosis; if positive, it may occasionally give information about activity in the suspected focus. The guinea-pig inoculation is not called for so often now that concentration and cultural methods are being perfected. Lipiodol gives satisfying results in bronchiectasis, frequently not even suspected, and in new growths and abscess. I give lipiodol by the crico-thyroid route. Beforehand the patient is tested for iodism and thirty minutes before the injection of lipiodol he is made to cough up all sputum, given morphia and atropine and placed on the X ray couch with a loaded cassette beneath. A local anæsthetic is given, the oil is injected, the patient tilted to left and right and the shoulders drooped a shade during the injection. The film is exposed and at once the patient is screened and if sufficient oil is in, a stereo in the upright position is taken. There are few after-effects; but a cathartic is administered.

The sanatorium ought perhaps to have a bronchoscope.

Treatment.

The further treatment prescribed for the patient may be traditional sanatorium routine, tuberculin, sanocrysin, collapse therapy, or a combination of these methods.

TRADITIONAL ROUTINE.

Where possible, the traditional routine is applied to all cases. Treatment is controlled by accurate temperature and pulse record. The physician visits the patient daily, but valetudinarism is eschewed. Meals are regular and ample, and snacks are abolished. Air is abundant, but protection recommended. Rest is the keynote, for the better the rest the better the chance of recovery; and so lights are out by 8 P.M., and no routine nursing duties may begin until after 7 A.M.—eleven hours of quiet! This means untidy wards for the 9 A.M. round, yet what does that matter? Patients are more important than doctors and matrons. Strict rest for an hour before meals is enforced and the "cure" hours—ten to twelve and two to four—are rest hours for bed patients. Bed or absolute rest is enjoined until symptoms, temperature, and pulse warrant an advance. "Hurry slowly" is the best method. The diurnal swing of the temperature should not exceed one degree and its acme be not above 98·6°. The pulse rate should not exceed 86; but, of course, there are occasional exceptions.

Ultimately patients are allowed up for one hour and hour is added to hour until the patient is up for four hours, when occupational therapy—a handicraft—commences. When the patient is up all day, walks, games, and work are prescribed and this grading of the patient should be zealously performed and must cover games. The occupational therapy is insisted upon, for there is nothing to equal it in maintaining hope and the habit of work. Idling is as bad physically as it is morally. When the patient can do about six hours' work easily, is symptomless, with weight above normal, the sputum negative and the sedimentation rate normal, discharge is recommended, for this is quiescence. Many of the present type of case never attain to this and are discharged to their home or hospital as "improved" or "worse."

Each month the patient is re-examined by the medical officer and the sputum tested. Every two months, in addition, the sedimentation rate is graphed and at the end of three months a further radiogram is taken and the case reviewed completely at the clinic. At this review special attention is paid to the state of the sputum, the sedimentation rate graphs, and the X ray films.

SANOCRYSIN.

Occasionally I use tuberculin; but apart from saying that I still think this is a dangerous remedy, I pass to another dangerous drug—viz., sanocrysin—a double salt of gold prepared by Mollgaard, of Copenhagen. I have formed a very high opinion of the drug and use it in recent exudative cases, chronic cases with a recent exacerbation or spread, in artificial pneumothorax cases where the opposite side is diseased already or flares up during treatment and, though of lesser value, in chronic cases of fibrotic character with persistent tubercle bacilli. I think it useless in the face of an uncontrolled cavity and it should not be given when renal and intestinal complications are present.

This drug is given intravenously twice weekly, and the patient is kept in bed for the whole course, which takes about eight weeks. I use small doses, and the laboratory keeps a sharp look-out on the liver and kidney by means of a daily liver function and a delicate albumin test. The excretion of the drug is slow, and therefore we allow eight weeks' interval between two courses, and the second course is given only if there is radiological evidence of clearing. The dangers are those of administering a heavy metal.

All cases given sanocrysin by us were Turban 3—that is, advanced and many hopeless, and nearly all had tubercle bacilli in the sputum. In one series, followed up, both immediate and after-results are superior to sanatorium treatment alone, and the striking feature is not merely the alteration in the character of the tubercle bacilli but their disappearance from the sputum. For example, if we take cases treated by all methods, including sanocrysin, tubercle bacilli disappear in 39 per cent., whereas in cases treated by sanocrysin alone they disappear in 58 per cent., and we know from all sanatorium statistics how much better the after-results are when the tubercle bacilli are eliminated from the sputum. Despite the very advanced type which we treated by sanocrysin we get, after two years, the same excellent results in cases where cavities were controlled by other means, as in the cases who ha extensive trouble but no cavities—viz., 93·75 per cent. are alive, 69 per cent. are actually at work. This result in the worst type of case must suffice to demonstrate the value of sanocrysin, as space prohibits a complete analysis in this paper.

COLLAPSE THERAPY.

The aim of collapse therapy is to apply rest to the diseased part so that toxæmia may be controlled and healing promoted. Some simple methods of resting the diseased lung are efficiently strapping the side, firmly bandaging, applying sandbags, and for the patient always to lie upon that side. Some of the special methods are artificial pneumothorax, phrenic avulsion, and thoracoplasty.

ARTIFICIAL PNEUMOTHORAX.

Artificial pneumothorax is the method of choice. The rapidity with which a patient improves and the excellent after-results have established artificial pneumothorax as the greatest advance in the treatment of pulmonary tuberculosis.

A gas, usually atmospheric air, is passed into the pleural cavity at a known pressure, which is made possible by an apparatus that first measures the air given and records the pressures by a manometer. I do not propose going into questions of instruments and technique. The air is absorbed at different rates by different patients and so refills of air have to be given. The aim is not to compress the lung against the root, but to collapse the diseased portions and so put them out of action and permit partial but sufficient rest to abolish symptoms. This is the optimum pressure. I believe in giving small quantities of air, about 300 c.cm. and frequent refills if necessary, so that the lung rest is kept fairly constant. The pleura in time becomes more and more impervious to air and refills therefore less frequent. The treatment may have to be maintained for three or more years, but of course, the patient is an out-patient, and yet this long treatment is really the shortest treatment I know for pulmonary tuberculosis.

The indications for artificial pneumothorax are numerous. The classical case is the one-sided case, but I rarely see this type and my indications have been extended to include the very advanced and progressive cases, nearly all patients with cavities and hæmorrhages and laryngeal involvement. The limited lesion, if there be no cavities, is exempt from this treatment. It is sometimes applied simultaneously to both sides, sometimes to one side first, and later to the other.

There are some operative dangers—e.g., pleural shock and air embolism—but these are surely rare, for in my 1100 artificial pneumothorax patients I have not as yet met them. There are complications, particularly fluid, and this, in my opinion, is more than a nuisance and demands removal by air replacement and the pleural cavity bathed with methylene-blue, acriflavine, or alepol. There are difficulties, such as a mobile mediastinum and pleural adhesions, which demand special methods such as oleothorax and cauterisation respectively.

In the control of artificial pneumothorax I think radiography is essential, though without X ray control the treatment is possible, but undesirable. The screening of a case at each refill gives much more information about the diseased side than a photograph does; but a radiogram is needed at least every three months to give data about the uncollapsed side.

When artificial pneumothorax patients are discharged from the sanatorium, they once again come under the practitioner's supervision. They should be encouraged to observe sanatorium routine and to continue with refills. If a sudden temperature develops, suspect fluid, even pus; but do not interfere until symptoms demand it, and if possible, send such cases as emergencies to the sanatorium. Should this be impracticable, spare the ribs at first and remove the fluid with a Potain's or other aspirator, and to do this place the patient in a sitting position. Gain entrance high in the axilla with the cannula and dip it downwards to the diaphragm. Introduce an ordinary 5 c.cm. syringe needle into the pleural cavity above the cannula and lightly plug it with cotton-wool. This needle allows air to enter as fluid comes off. To leave fluid untouched when distress occurs may lead to such a pressure that both an external and a broncho-pulmonary fistula may result —grave complications.

If there is sudden gross dyspnœa and distress, suspect spontaneous pneumothorax; the physical signs when such a condition is superimposed are so protean in character that they cannot be hinted at here. Act upon suspicion and insert a 10 c.cm. syringe needle into the affected side and if necessary play upon it—i.e., as the patient breathes keep a finger on the lumen of the needle for inspiration and off it for expiration. Spontaneous pneumothorax, however, may occur in the opposite side when the physical signs are more obvious and similar emergency treatment should be given.

Occasionally bronchitis or pneumonia may supervene on the contralateral side. The new condition should be treated on the usual lines, and if acute symptoms occur one should resort again to the 10 c.cm. needle on the pneumothorax side.

When is the pneumothorax to be abandoned? Unfortunately, many will obliterate too early. The time to abandon the others is not a matter of empiricism, but of trial under careful control. Excellent if the patient can be readmitted to the sanatorium for the trial but this is rarely done. When it is resolved to abandon, the interval of refill is extended and the patient encouraged to report any return of symptoms and the physician to seek for the return of signs. Please weigh your patient weekly at this critical time and question him closely, and if your trained eye notices anything amiss kindly report it, for the tuberculous is anxious to finish his treatment and often prepared to run the risk. "Look around the habitable globe and see how few know their own good or knowing it pursue."

If artificial pneumothorax fails it is usually because of pleural adhesions. This happens in 20 per cent. of my cases, and in order to give an impression of the after-history I must be content with saying that only 9 per cent. of these cases are at work and even these all had a phrenic avulsion. In patients, on the other hand, with a useful collapse, surely comparable or control material, 46 per cent. are at work. I do a phrenic avulsion on the pneumothorax side as a routine, unless it has been necessary to perform it on the opposite side, as it gives additional rest, spreads out refills, and limits the size of the hemithorax—a desideratum to save stress on fibrous tissue when the pneumothorax is obliterated.

PHRENIC AVULSION.

This is the operation of removing the phrenic nerve in its entirety. Simple section of the nerve is inadequate because more than 25 per cent. of all people have an accessory phrenic which would still activate the diaphragm. Under local anæsthesia, the nerve is sought through a half-inch incision in the neck, gripped, the proximal end cut, and then, by traction and twisting, pulled out—if possible in its total length, and aiming to remove at least 10 cm. and so be sure of destroying the accessory phrenic.

Phrenic avulsion, or a "phrenic" as it is familiarly called, I perform in almost any case with extensive trouble, and it is my stand-by in the artificial pneumothorax failures. It may be performed on one side and a pneumothorax on the other. It is normally undertaken before a thoracoplasty, and is useful to relieve persistent symptoms—e.g., cough, hiccough, and pain—and it may be performed as a last resort. The result of a successful "phrenic" is to paralyse the diaphragm which then rises steadily for at least four months to a variable height, occasionally as high as the third rib in the mid-axillary line. The diaphragmatic muscle atrophies. The flaccid diaphragm may have paradoxical movement due to a "push up" by the abdominal viscera as the normal diaphragm descends, but the flaccid diaphragm is always high. Cough is easier and, whichever side is paralysed, there is no interference with the act of defæcation and rarely, if ever, disturbance of stomach function.

I value phrenic avulsion highly and the results have been much better than I anticipated—e.g., 75 per cent. of cavities are affected as against 12 per cent. of sanatorium routine. But I do not resort to the operation in early cases, neither do I think it the method of choice, except for nervous and mentally deficient people who would not face an artificial pneumothorax with equanimity.

THORACOPLASTY.

This is the name that covers a variety of operations for the removal of ribs, so that the underlying lung may be collapsed. The thoracoplasty may be partial or complete according to the number of ribs removed. The good surgeon plans his operation to give the desired collapse. In some cases a few ribs will suffice, in others six or seven, and in others all will have to be resected. I shall not describe any of the operations. A complete thoracoplasty is a serious operation with a 5 per cent. mortality, but tuberculosis is a serious disease, and as the technique of the operation is steadily improving, so the operative mortality is lessening. If all cases were found when early it would mean very few artificial pneumothoraxes and phrenic avulsions and still fewer thoracoplasties. Since, however, patients once early and curable, for one reason or another become advanced something must be done, for we know the fate of the untreated and advanced consumptive.

Thoracoplasty must not be done too early nor yet too late and never as a last resort. Artificial pneumothorax impracticable, phrenic avulsion insufficient, the only alternative *in a suitable case* is a well-planned thoracoplasty and it should not be recommended until then.

The selection of the case demands the greatest discrimination. A patient should usually not exceed 45 years of age and the heart muscle must be irreproachable. The opposite lung should be sound, though a little healed trouble may be ignored. The lung should show definite evidence of fibrosis and the exudative type is unsuitable. I recommend for the operation the patient faced with chronic invalidism, the one with a persistent positive sputum, he who has a thick walled cavity, a spontaneous pneumothorax with a patent opening or a tuberculous empyema. Persistent positive sputum is a danger to the patient and possibly to others. A thick walled cavity may be evidence of chronicity, but it must be collapsed. Tuberculous empyema rarely subsides with irrigation. If resection of ribs becomes necessary let it be done anteriorly, so that the fie is left clear should a thoracoplasty be advised.

Remembering the gravity of the case submitt for thoracoplasty the results are amazing—38 per cen are cured and a further 20 per cent. are alive. England many patients die for the want of a thorac plasty, for too few physicians recommend the operati and too few surgeons undertake it.

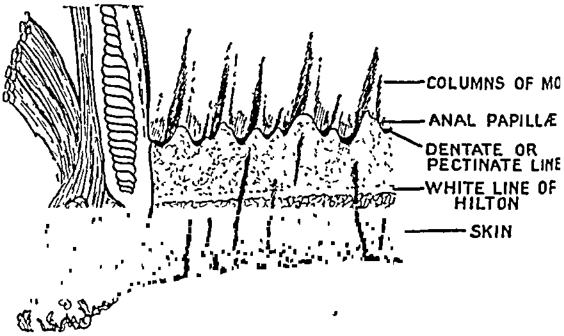
THE PECTEN: THE PECTEN BAND PECTENOSIS AND PECTENOTOMY.*

BY A. LAWRENCE ABEL, M.S. LOND., F.R.C.S. ENG

SURGEON TO THE PRINCESS BEATRICE HOSPITAL AND TO TH GORDON HOSPITAL FOR RECTAL DISEASES; ASSISTANT SURGEON TO THE CANCER HOSPITAL AND TO THE WOOLWICH MEMORIAL HOSPITAL.

THE "pecten" is the name given by Stroud[1] i 1896 to approximately the middle third of the an canal. The anal canal is the portion of the alimentar canal which leads from the lower end of the rectu to the exterior. It commences in both male an female at the level of the median borders of th levator ani muscles. In the male it is opposite th inferior part of the prostate. In a state of repos the anal canal is a slit-like passageway, kept close by the compression of its upper end by the levator a muscles, and below these by the compression of the internal and external sphincter muscles. During defæcation it becomes oval in shape and shorter. Its normal length is one and a half inches, and its antero-posterior diameter three-fourths of an inch. The direction taken by the anal canal is downwards and slightly backwards in a line drawn from the umbilicus to the anal aperture.

FIG. 1.



INTERIOR ANATOMY OF ANAL CANAL.

When an examination of the interior of the anal canal is made, about half an inch up from the anal verge, a distinct white line is seen (Fig. 1). This was first described by Hilton[2] in 1863, who says:

> "A white line, which in the living subject any surgeon can recognise, shows the junction of the skin and the mucous membrane. That white line corresponds exactly to the lineal interval between the external and internal sphincter muscle. It is an important landmark, exact and truthful, so that it can be relied upon."

Below the level of Hilton's "white line," the anal canal is lined by squamous epithelium, indistinguishable from ordinary skin, and the white line is often referred to as the muco-cutaneous junction.

Immediately above Hilton's white line is an area varying in breadth from one-eighth to one-third of an inch, the colour of which is intermediate between that of the skin and the mucous membrane of the rectum. Stroud has given this zone the name of the "pecten," because arising from its upper edge, like the teeth of a comb (Latin, *pecten*), are the anal papillæ, which are continuous above with the columns of Morgagni, or columnæ rectales. The epithelium covering the columns of Morgagni is of the columnar variety similar to that of the remainder of the intestine. At the bases of the columns of Morgagni on the anal papillæ the columnar epithelium undergoes a change, and becomes transitional stratified epithelium for a distance of about a quarter of an inch, becoming squamous epithelium immediately below Hilton's white line. The bases of the anal papillæ are connected by a number of faintly marked irregular semilunar folds, which are known as the anal valves. These form a number of small pockets, or sinuses, between the vertical columns, and are known as the crypts of Morgagni. In other words the upper two-fifths of the anal canal is occupied by the columns of Morgagni covered by columnar epithelium. Approximately the middle one-fifth is the pecten. In a normal subject this has a glistening appearance, is quite smooth, and is almost entirely devoid of sweat glands. Above it is bounded by the wavy dentate or pectinate line caused by the anal papillæ, and below by Hilton's white line. The lower two-fifths of the anal canal is lined by squamous epithelium.

---

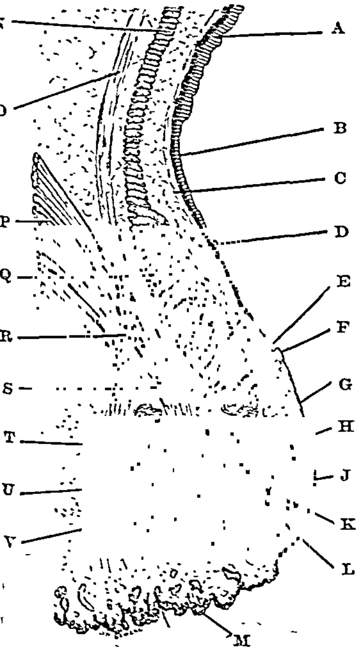
* A paper read before the Subsection of Proctology of the Royal Society of Medicine, on Jan. 13th, 1932.

The importance of this portion of the anal canal may be judged by the statement of Pennington,[3] who estimates that 85 per cent. of all proctological diseases occur in this area.

DEVELOPMENT.

The pecten marks the union of the proctodeum and the hind gut. The part below the pecten is formed by an ectodermal depression named the proctodeum; the part above this line is formed from the hind gut. The part of the hind gut caudal to the allantois is frequently termed the cloaca, and in the early embryo it is separated from the ectoderm by the cloacal membrane. The part of the cloacal membrane which separates the rectum from the ectodermal pouch or proctodeum is known as the anal membrane. During the fourth month of intra-uterine life the anal membrane ruptures and so the rectum and anal canal communicate. Non-perforation of the normally formed anal membrane situated at the level of the pecten constitutes one of the varieties of imperforate anus.

FIG. 2.



A = normal columnar epithelium of rectum. B = columnar epithelium of upper part of anal canal. C = muscularis mucosæ. D = superior hæmorrhoidal plexus. E = anal valve. F = pectinate or dentate line. G = epithelium of pecten. H = white line of Hilton. J = skin of anal canal below Hilton's line. K = gland in external sphincter muscle (a similar gland is seen in the internal sphincter). L = inferior hæmorrhoidal plexus. M = normal skin beyond anal verge, with sweat glands and hair follicles. N = inner circular fibres of bowel wall. O = outer longitudinal fibres of bowel wall. P = levator ani muscle. Q = internal sphincter muscle. R = blending of O and P. S = inner tendon passing between two portions of external sphincter muscle. T = outer tendon passing to outer side of external sphincter. U = inner portion of external sphincter muscle. V = outer portion of external sphincter muscle.

Composite semi-diagrammatic scheme of relations of anal canal from sections kindly lent by Dr. Cuthbert Dukes.

FIG. 3.

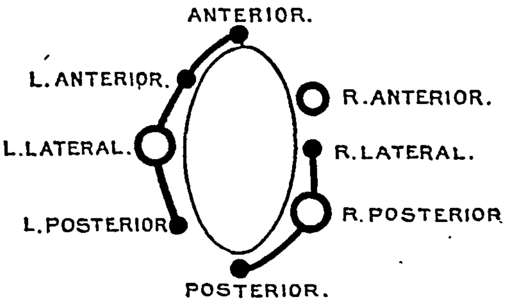


Diagram showing position of arteries in the anal canal. These, together with their venæ comites, form internal piles, as follows: those indicated by large circles (the main vessels) form primary piles; those indicated by small circles form secondary piles.

EXTERNAL RELATIONS.

Immediately to the outer side of the pecten is the slight depression between the internal and external sphincter muscles and the lowest fibres of the internal sphincter (Fig. 2). Below and to the outer side of the pecten can be felt the external sphincter muscle. Above and more laterally the fibres of the levator ani muscle and the outer longitudinal fibres of the bowel wall blend together and pass downwards in two portions: (1) through the external sphincter, dividing it into two portions, superficial and deep; (2) lateral to the muscle forming an external capsule for it.

Above the level of the pecten lies the internal sphincter muscle, composed of a thickening of the inner circular layer of fibres of the intestinal wall.

VASCULAR SUPPLY OF THE PECTEN.

Terminal arterioles and capillaries of the superior, middle, and inferior hæmorrhoidal arteries reach the submucosa of the pecten (Fig. 3). Accompanying these are their corresponding venæ comites. The superior hæmorrhoidal arteries and veins are the most important because of their relation to internal hæmorrhoids, and because they occupy constant positions in relation to the circumference of the anal canal. From the superior hæmorrhoidal artery arise two primary branches, a right and a left. The right branch penetrates the muscular coat, and after entering the submucous tissue divides into an anterior and a posterior branch. The anterior branch passes downwards in the right anterior quadrant of the rectum, and never gives off any further branches. The posterior branch passes downwards in the right posterior quadrant and on its way gives off two branches: an anterior, which runs down in the middle of the right side of the anal canal, and a posterior, which passes downwards in the midline posteriorly. On the left side the artery after piercing the muscular coat, passes downwards in the middle of the left side of the anal canal. It remains single until near its termination, when it gives off two branches, an anterior, running downwards in the middle of the left anterior quadrant, and a posterior, running in the middle of the left posterior quadrant. Very rarely the left anterior branch of the left branch of the superior hæmorrhoidal artery gives off a further branch which lies in the anterior portion of the anal canal. The main branches of the superior hæmorrhoidal artery, together with their accompanying venæ comites and venous plexuses, take part in the formation of what are called primary hæmorrhoids, which are therefore situated in the right anterior, right posterior, and left lateral aspects of the anal canal.

Branches of these main branches give rise to the secondary hæmorrhoids—namely, from the right posterior artery; right lateral and posterior secondary hæmorrhoids; from the left lateral; left anterior, left posterior, and very rarely anterior secondary hæmorrhoids. No secondary hæmorrhoids arise from the right anterior main branch.

Thus if all possible hæmorrhoids are developed the pecten marks the lower limit of three primary and five secondary hæmorrhoids.

The pecten also marks the dividing line between the superior hæmorrhoidal vessels above, and the inferior hæmorrhoidal vessels below (Fig. 4). That is to say, the small vessels in the submucosa of the pecten communicate with both the portal and systemic circulations.

Intero-external piles are a varicose condition of both superior and inferior hæmorrhoidal plexuses united together by a varicose condition of the communicating veins in the submucosa of the pecten.

Below the level of the pecten lies a venous ring, the inferior hæmorrhoidal plexus, which is formed by numerous small vessels arising from the submucocutaneous tissue, situated at the level of Hilton's white line. The majority of these twigs pass superficial to the external sphincter while others pass between its superficial and deep portions. Running beneath the mucous membrane of the pecten are a number of small veins which form the communication between the superior and inferior hæmorrhoidal plexuses. These small veins are apt to become dilated by constant straining, and when one is ruptured it forms the so-called ruptured external pile, often erroneously called the thrombotic pile, the more modern term for which is "hæmatoma ani." If suppuration occurs in one of these veins, a fistulous track may be formed which may be either entirely internal to the external sphincter, or may lie between its superficial and deep portions. The middle hæmorrhoidal plexus of veins lies on the outer surface of the rectum immediately above the levator ani muscle. A few small vessels from the superior hæmorrhoidal plexus communicate with the middle hæmorrhoidal plexus through the internal sphincter muscle.

NERVE-SUPPLY OF THE PECTEN.

The pecten is also the dividing line between the cerebro-spinal and sympathetic nerve-supply of the anal canal and rectum. The pecten and the anus are supplied by means of cerebro-spinal nerves from the third, fourth, and fifth sacral nerve. A large proportion of the terminations of these nerves end in the anal papillæ of the pecten. These papillæ, which are peculiar to man, consist chiefly of nerve-fibres and ganglion cells. Most observers consider that these papillæ constitute an accessory sense organ of a higher degree of development than the rest of the pecten. The whole of this area is very sensitive to pain.

Above the region of the pecten the anus and rectum are supplied through the sympathetic nerves in a manner similar to that of the rest of the intestine, and sensation to pain is almost entirely absent.

LYMPHATICS OF THE PECTEN.

The pecten is also the dividing line between the somatic and visceral lymphatics. Distal to the pecten the lymphatics drain into the inguinal nodes, while proximally they drain into the sacral and lumbar lymph nodes.

The lymphatics from the pecten form a plexus situated in the submucous plane and in the intermuscular plane. Efferents from these communicate with three groups: (1) the lymph sinus of the rectum, situated outside the external muscular coat of the rectum; (2) the subcutaneous peri-anal lymphatics, efferents of which pass either immediately beneath the skin or between the superficial and deep portions of the external sphincter muscle; (3) directly laterally between the two sphincters, through the fatty tissue of the ischio-rectal fossa to reach Alcock's canal.

This leads me to mention the types of fistulæ, the internal openings of which are situated in the pecten. The internal opening of a blind internal subcutaneous fistula is situated at the lower edge of a fissure, which lies as a rule on Hilton's white line. The same is true of the internal opening of a complete subcutaneous fistula. A blind internal submucous fistula has its internal opening in the pecten, as does also a bilateral submucous fistula. The blind internal intramuscular ano-rectal fistula also has its internal opening about a quarter of an inch above Hilton's white line. All blind internal and complete subsphincteric fistulæ, and blind internal and complete ischio-rectal fistulæ, have their internal openings in the pecten.

FOCAL INFECTION.

The anal crypts of Morgagni, which form part of the pecten, form little saccules in which bacteria and small foreign bodies may lodge. Here also open the mouths of the submucous and intermuscular glands described by H. A. Harris[4] and Sir Charles Gordon-Watson. Irritation in the region of the pecten causes tenesmus and neuralgia of the rectum. It is customary to classify diseases proximal to the pecten as "visceral diseases," and those distal as "perineal." Pennington believes that in this area toxins may be given off from the lodged bacteria, and disturbances of reflexes originate at this level, and perverted function of the intestine may also be initiated. He also points out that diseases peculiar to the epidermis occur distal to the pecten but not on the proximal side. Diseases peculiar to the mucosa are found only on its proximal side.

The pecten also marks the proximal boundary of pruritus ani, and is the dividing line between external and internal hæmorrhoids. Infection in this region may travel either via the portal or the systemic, or both, venous systems.

THE SPHINCTERS.

The two sphincters of the anal canal are true sphincters, and the act of defæcation is performed mainly under the influence of the parasympathetic portion of the autonomic nervous system. Stimulation of this produces effects directly the reverse of those resulting from stimulation of the sympathetic portion. The physiological processes which take place on sympathetic stimulation are an inhibition of peristalsis and spasmodic contraction of both the sphincters of the anus.

Throughout the animal world these occur during muscular exercise, especially during the search for food and in mortal combat; and in human beings at times of mental concentration, especially when accompanied by worry or grief. The parasympathetic nervous system, on the other hand, should come into play at a time of both physical and mental repose, when the function of the sympathetic portion is relatively in abeyance. The effect of the ingestion of food into the stomach causes a gastro-colic reflex which normally only takes place once a day immediately the first meal of the day is ingested. This originates active peristalsis of the large intestine, and relaxation is brought about, first by the direct action of the longitudinal fibres, and secondly by a diminution of the tone of the sphincters, an inhibitory reflex caused by the peristalsis of the whole colon. This reflex arch may be disturbed either on the side of the parasympathetic system, or more commonly on its sympathetic portion, or by a central, cerebral, or psychic effect acting upon either or both.

Hilton says:

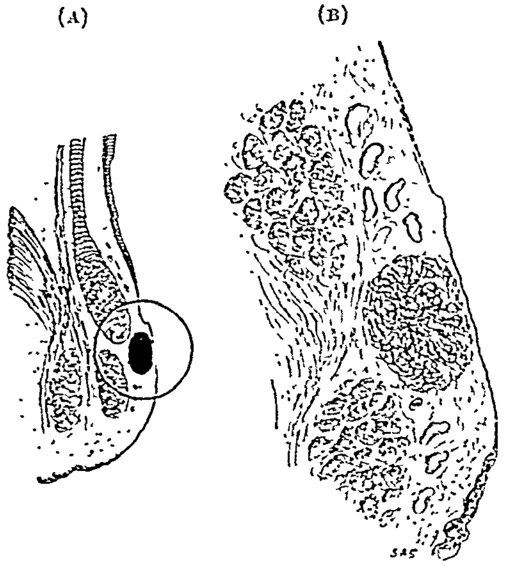
> "Who is there that has not felt this kind of competitive struggle, this intestinal warfare going on within himself, fearing the issue and has not been thankful for the result, and full of gratitude for the enduring strength of the little indomitable sphincter, which has averted the possible catastrophe?"

THE "PECTEN BAND."

The anal sphincters, in common with the other sphincters of the alimentary canal, not only have the power of maintaining their normal tone, and exhibit the function of relaxation due to inhibitory reflexes, but can also be thrown into a state of hypertonus or spasm. Sphincteric tissue is an area where normal or excessive tone can be maintained indefinitely without the muscle at this level becoming hypertrophied, and it is the musculature proximal to it which hypertrophies if the sphincter is in a state of hypertonus, that is, a state of spasm. It would appear that sphincters which are under the control of the will pass into a state of spasm more readily than those which are not under the control of the will, and that spasm occurring in voluntary sphincters is apt to be of a more prolonged nature, and to be followed by more serious results than spasm of an involuntary sphincter. I refer especially, of course, to the crico-pharyngeus muscle, the superior sphincter of the œsophagus, and to the external sphincter of the anus.

Hypertonicity or spasm occurring in the alimentary canal produces a local passive congestion which ultimately results in fibrous induration. It has been already pointed out that the tributaries of the superior and inferior hæmorrhoidal veins arise from a minute capillary plexus situated in the submucous tissue of the pecten. When the flow of blood from this minute plexus is obstructed, either by a spasm of the external or internal sphincter or both, the plexus becomes the seat of passive congestion. This results in a deposition of fibrous tissue taking place in the submucous tissue of the pecten. Quite apart from spasm of the sphincters, we know that varicose veins in any situation may lead to passive congestion in the tissues from whence they arise. This ultimately results in the deposition of fibrous tissue, following a round-celled infiltration. Evidence of such induration, as a sequel to passive congestion, is well exemplified in the case of the indurated zone in the neighbourhood of a varicose ulcer of the leg. A similar deposition of fibrous tissue occurs after a varying amount of time in subjects who have internal hæmorrhoids (Fig. 5). Occurring in the anal canal, this condition was first described by W. E. Miles [5] in the following terms:

FIG. 5.



(A) Section through anal canal showing pecten band in relation to normal structures. (B) Microscopical view of portion of A enclosed by circle. Note: above and below, fibres of internal and external sphincter muscles respectively; right centre, organised fibrous tissue forming pecten band; above and below this, veins of superior and inferior hæmorrhoidal plexuses respectively.

> "The fibrous deposit takes the form of a circular band varying in thickness and density, completely surrounding the lower part of the anal canal, and situated between the mucous membrane of the pecten and the external sphincter muscle. In well-marked instances the band of fibrous tissue can be distinctly felt, and gives an impression to the examining finger such as would be obtained if a rubber umbrella ring had been inserted beneath the skin at the anal margin. I have named this deposit of fibrous tissue in the submucosa of the pecten 'the pecten band.' The pecten band does not exist in the healthy anal canal. It is purely pathological in origin."

I have elsewhere [6] called attention to an exactly similar deposit of fibrous tissue, which occurs at the level of the crico-pharyngeus muscle, in cases of long-standing so-called globus hystericus, as a result of the passive congestion produced by long-continued spasm of the crico-pharyngeal sphincter. It was first described in 1918 by Dan McKenzie,[7] and has been described by many surgeons since. It diminishes the expansibility of the gullet, and gives rise to painless dysphagia, which is, or may have been for many months, a precursor of a hypopharyngeal neoplasm. A very similar condition occurs at the cardiac sphincter in cases of cardiospasm, and as the cardiac sphincter is from one to one and a half inches in length, a definite band is seldom found but considerable fibrosis occurs in the wall of the œsophagus opposite the whole length of the cardiac sphincter. The condition occurring in the post-cricoid region is known as post-cricoid spasmodic stricture, and is frequently followed by marked anæmia and splenomegaly.

A similar analogy might be drawn between the spasmodic hour-glass stomach, situated opposite a gastric ulcer, which subsequently becomes an organic hour-glass stomach, due to the deposition of dense fibrous tissue as a result of a long-continued spasm and consequent passive congestion.

RELATION OF THE PECTEN BAND TO RECTAL PATHOLOGY.

Passive congestion in the region of the pecten may be brought about by a number of factors. Probably the commonest is the varicosities of the superior hæmorrhoidal veins. Constipation alone without the presence of hæmorrhoids has an exactly similar effect, as has also spasm of the sphincter muscles. With the passage of months and years the pecten band becomes more and more dense, and prevents the proper relaxation of the sphincters. There is then difficulty in obtaining complete emptying of the rectum, the size of the calibre of the fæces is diminished, and the lower half of the anal canal tends to be held immobile, while the elevating effect of the pubo-coccygeal part of the levator ani muscle has the effect of pulling the internal away from the external sphincter, thereby causing sometimes as much as an inch of separation between the two sphincters, and still further increasing the difficulty in obtaining complete emptying of the rectum during defæcation. The tighter the anal aperture becomes, the greater the straining at stool; hence any hæmorrhoidal condition tends to be aggravated, and if the piles become prolapsed through the anal orifice they are apt to become strangulated by the non-yielding pecten band. As a result of this deposit of fibrous tissue in the submucosa of the pecten, the mucous membrane of this region, instead of being freely movable over the subjacent tissues, becomes anchored to it and poorly nourished with blood. This renders it much more easily damaged than in a normal subject. It is uncommon to find a fissure in a patient without a pre-existing pecten band. If the anus is everted in a patient suffering from fissure definite white strands of fibrous tissue can be discerned running circularly around the anal canal at the bottom of the fissure; and if a portion of this tissue is taken for microscopical section it will be found to consist of fibrous tissue only.

We have noticed how the post-cricoid spasmodic stricture produces, after a considerable time, a thin and atrophic mucous membrane in the pharynx, and may eventually lead to malignant disease. The mucous membrane of the rectum frequently becomes unhealthy in patients with long-standing pectenosis; secretion of normal rectal mucus is apt to become excessive, and the patient suffers from pruritus ani. When no other pathological condition exists in the rectum, pruritus of these patients may be cured by performing the operation of pectenotomy. It is interesting to speculate that sometimes the pecten band may be responsible for the development of carcinoma in the altered mucous membrane of the rectum. Cracks or fissures in the region of the pecten are by far the commonest portal of entry of micro-organisms into the lymphatics and veins of the anal canal, and thence to the tissues around the anus, giving rise to ano-rectal abscesses and fistulæ. A careful examination of many of these cases reveals not only the internal opening in the pecten, but also a definite pecten band in the same region, and there is no doubt that pectenosis is the most frequent precursor of ano-rectal fistulæ.

The pecten band may exist to a marked degree without any other pathological condition being found in the rectum or anal canal. When this condition is allowed to progress, the anus may become almost completely closed. I have seen three cases of typical acute intestinal obstruction, which were produced by a severe pectenosis, and which were entirely cured by the operation of pectenotomy. Many years must elapse before the pecten band contracts to such an extreme degree. Two of these patients were over 70 years of age, and one was a man of 80.

PECTENOTOMY.

The old-fashioned procedure of stretching the sphincters produces a rupture of the fibres of the pecten band in many places, usually with multiple areas of extravasation of blood amongst these fibres, and consequently the further formation of fibrous tissue, and ultimately a thicker and denser pecten band results. This, however, is not always the case, for if little hæmorrhage occurs, complete relaxation of the sphincters is obtained, a normal functioning of the anal canal may be instituted, and the fibrous deposit may be reabsorbed.

A much more satisfactory and certain method is to make a clean incision through the pecten band. No hidden areas of hæmorrhage are left to fibrose and contract; the sphincters are restored to their full powers of relaxation; the interval is filled in by thin granulations, and within a short time the whole of the pecten band is reabsorbed, and a healthy mucosa of the pecten results. For this reason pectenotomy is preferred to so-called stretching of the sphincters, and in attempting the cure of a fissure division of the external sphincter muscle is never necessary, except in very long-standing cases, when the fibrosis has extended, not only to the submucosa of the pecten, but also into the substance of the external sphincter muscle, as it sometimes does. Should it be necessary to cut the external sphincter no impairment of control results.

The operation of pectenotomy is usually performed with the patient lying in the right lateral position. The index-finger of the left hand is inserted into the anal canal without lubricant. The right posterior quadrant of the anal canal is everted. A little to the right of the midline an incision is made parallel to the long axis of the bowel, the upper end being situated half an inch above Hilton's white line, and its lower end a short distance below this line. Immediately the mucous membrane and skin have been divided, the white fibres of the pecten band come into view, at the upper end of the wound, and the reddish-brown fibres of the external sphincter may just be seen at the lower end of the wound. The latter are carefully avoided, and the incision is carried deeper until the complete thickness of the dense fibres of the pecten band is divided. Immediately this is done the anus is found to be relaxed, in common with the other muscles affected by the general anæsthetic, and two or three fingers can easily be passed into the anus, whereas before the pectenotomy, great difficulty may have been experienced in even passing the index-finger.

THE
ACTIVE PRINCIPLE IN HOG'S STOMACH EFFECTIVE IN PERNICIOUS ANÆMIA.

By John F. Wilkinson, M.D., M.Sc., Ph.D., F.I.C.,
DIRECTOR OF THE DEPARTMENT OF CLINICAL INVESTIGATIONS AND RESEARCH, UNIVERSITY OF MANCHESTER (MANCHESTER ROYAL INFIRMARY);

AND

Louis Klein, M.Sc., Ph.D., A.I.C.,
BIOCHEMIST IN THE DEPARTMENT.

The value of hog's stomach in the treatment of pernicious anæmia has been amply demonstrated during the last two and a half years by workers in many countries.[1] [2] There is, however, little resemblance to the corresponding liver therapy so far as the active principles involved are concerned. From liver palatable and concentrated extracts are readily obtained,[3] but similar preparations have failed in our hands with stomach tissue, and this observation has been confirmed by Meulengracht.[4]

In the course of early experiments on raw stomach during 1929 it soon became apparent to us that certain essential conditions were necessary for the production of active stomach preparations. These were such as one would expect to obtain if the activity were due to a substance which was relatively unstable, and similar in this and possibly other respects to enzymes. From an entirely different viewpoint, an examination of the behaviour of normal gastric juice under varying conditions [2] [5] gave rise to a similar idea with regard to the active principle which Castle terms the "intrinsic factor" present in human gastric secretions. In the present paper we are concerned with the investigation of the active principle present in hog's stomach.

It will suffice here to mention that in our early experiments several procedures were found to yield inactive stomach extracts. Of these the following may be mentioned:—

1. Exposure to a temperature of more than 45° C. at any stage.
2. Autolysis, especially in the presence of free hydrochloric acid, for a greater or less number of hours, depending upon the temperature.
3. Prolonged digestion with pepsin and hydrochloric acid, or trypsin, under most conditions.

It was appreciated at the outset that whatever its constitution the active substance would be present in relatively small quantities, and large bulks of raw material would require to be worked up if any success was to be achieved in isolating it.

It is not proposed to describe here all the various methods of extraction that were tried, but the main ones will be indicated. As each step in the experiments has furnished fractions, they have been administered to suitable cases of pernicious anæmia for control as to their hæmopoietic activities. The cases used for this purpose were all carefully chosen according to the rigid criteria already laid down,[6] and this has of necessity made progress slow.

EXTRACTS OF DESICCATED HOG'S STOMACH.

Large-scale experiments were tried first with the desiccated hog's stomach, since it was more easily handled than the fresh organ.

1. Dilute hydrochloric acid at different pH values, with and without the addition of pepsin or glycerin, failed to furnish a solution that would initiate remissions in cases of pernicious anæmia. On the other hand, the solid residues when separated and desiccated were still active.
2. The use of organic solvents likewise failed to furnish any active extracts. Thus 4·5 kg. of desiccated stomach lost about 10 per cent. of its weight after ether extraction. The ethereal extract consisted of hæmopoietically inactive fat. Subsequent extraction with varying strengths (60–70 per cent.) of ethyl alcohol removed less than 10 g. of sparingly soluble, lipoidal solid (m.p. 175–185° C.), and furnished an inactive thick, yellowish-brown fluid; both were hæmopoietically inactive. The residual stomach powder was still as active as the original powder even after seven months of continuous extraction with cold dilute alcohol (60–70 per cent.). Other organic solvents similarly failed.
3. The direct treatment of the desiccated stomach powder with such reagents as phosphotungstic acid and picric acid likewise did not furnish a clinically active product.

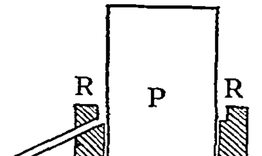
EXTRACTS OF FRESH STOMACH.*

Various methods of extracting the fresh tissue were investigated using water, dilute hydrochloric acid of various strengths, and glycerin. The following are brief details of an illustrative experiment.

Fresh minced hog's stomachs (367 kg.) were extracted three times with 660 litres of water adjusted to pH 4·6 by the addition of hydrochloric acid. The resulting liquor was concentrated at 40–45° C. in vacuo, made alkaline with caustic soda, treated with basic lead acetate to remove proteins, and the excess of lead removed with sulphuric acid. After concentration, 17 litres of a reddish-brown extract were obtained. No hæmopoietically active fractions were isolated from these extracts. On the other hand, the semi-solid residues were desiccated and shown to be still active. Subsidiary fractionations were also tried employing picric acid, phosphotungstic acid, mercuric chloride, whilst autolysis of the mucous membrane under varying conditions failed to give any more favourable results. Thus in one experiment, the product of the autolysis of the tissue at 45° C. in the presence of hydrochloric acid did not initiate a remission in a case of pernicious anæmia after the daily administration of 300 c.cm. of the autolysate for three weeks.

EXPRESSED STOMACH JUICE.

The complete failure of all these and other undescribed methods to furnish an active extract suggested to us the possibility that the active principle might be of the nature of an intracellular enzyme. Consequently, attention was directed to the method used by Büchner [7] for the preparation of the enzyme zymase from yeast—namely, expression of the juice from the disintegrated cells by the application of great pressure. In our earlier experiments, an ordinary hand press was used, but the yield of expressed juice obtained in this way from minced hog's stomach was very small, and a number of other difficulties were experienced rendering the method of little use, while the juice so obtained was hæmopoietically inactive when tested clinically. A special apparatus, therefore, was constructed, capable of withstanding considerable pressure, applied by means of a tensile and compressive testing machine in the Engineering Department of the University. It consists essentially (see Figure) of:—



(*a*) A cylinder C of cast iron, of which the upper part is provided with a recess R and an exit tube E.1. The lower end of the cylinder wall is provided with radial and circular grooves.

---

* The raw material for the experiments in this group was kindly supplied by Benger's Food, Ltd., Manchester, and some extracted in part by Dr. Bullock for us.

(*b*) A base plate B of cast iron having a recess into which the cylinder is securely bolted. It is provided with an exit tube, E.2.

(*c*) An iron plate, L, perforated with very fine holes, and having radial and circular grooves cut out of its lower surface. These grooves and also those at the lower end of the cylinder C enable liquid to flow away easily. The plate L fits tightly in the lower end of the cylinder C.

(*d*) A steel piston P.

The finely minced fresh stomach tissue was thoroughly mixed with an equal weight of Calais sand, ground in a special mill to the correct consistency, and the soft "dough" then subjected to a pressure of approximately 2½–3 tons per square inch in the above apparatus until no further liquid could be obtained. Under these conditions we were able to collect good yields of the expressed juice; thus, for example, in a series of experiments the yield of juice was between 558 and 669 c.cm. per 1000 g. of fresh tissue.

Properties.—The expressed juice is a reddish, opalescent, rather viscid liquid containing a small amount of suspended matter which can be removed by filtration through cloth. It decomposes rapidly within 24 hours at ordinary temperatures, but keeps fairly well in a refrigerator for about five days.

The juice is distinctly acid towards litmus and has a pH of approximately 6·0. It coagulates with heat owing to the presence of proteins. It has a good pepsin content, but contains no rennin, amylase, lipase, or urease. The following protein tests were positive: biuret, Molisch, lead acetate sulphur test, Millon, Pauly, Adamkiewicz, p.-dimethylaminobenzaldehyde, ninhydrin, Sakaguchi, Folin phenol test, xanthoproteic. Precipitates were obtained with the usual protein precipitants (alcohol, acetone, phosphotungstic acid, picric acid, trichloracetic acid, metaphosphoric acid, tannic acid, and lead acetate).

This juice was shown to be very active in the treatment of pernicious anæmia in three cases after a daily dose of 150 c.cm. Thus in two cases the reticulocytes rose to 16·2 and 24·5 per cent. respectively on the ninth day after a preliminary control period of seven days; a third case showed an increase in reticulocytes, but the treatment was discontinued owing to nausea and other therapy was instituted.

CASE 206.—Maximum reticulocyte response, 16·2 per cent. on the ninth day of treatment. First day of treatment: red cells (R.B.C.), 1,700,000; hæmoglobin (Hb.), 46 per cent.; white cells (W.B.C.), 1800. Twenty-fifth day of treatment: R.B.C., 3,250,000; Hb., 84 per cent.; W.B.C., 5300.

CASE 207.—Maximum reticulocyte response, 24·5 per cent. on the ninth day of treatment. First day of treatment: R.B.C., 1,400,000; Hb., 36 per cent.; W.B.C., 3200. Thirty-fourth day of treatment: R.B.C., 3,600,000; Hb., 78 per cent.; W.B.C., 7600.

FRACTIONATION OF EXPRESSED JUICE.

The expressed juice described above having been proved active was subjected to further fractionation. Precipitation by adding 1 volume of juice to 5 volumes of 90 per cent. alcohol furnished a copious precipitate (P5) and an alcoholic filtrate; the usual yield of solid, P5, was 15–18 g. per 500 c.cm. of juice, 1 g. thus being derived from approximately 50 g. of fresh whole stomach tissue.

Properties of precipitate P5.—This light, cream-coloured powder was only partially soluble in water. The peptic activity showed that it contained approximately all the pepsin in the original expressed juice; rennin, amylase, urease, and lipase were absent. Nitrogen, phosphorus, traces of iron, calcium, and sodium were present, it contained 13·5 per cent. total nitrogen, and gave positive results with all the protein reagents mentioned above.

The administration of this powder to two cases of pernicious anæmia showed that it possessed considerable hæmopoietic activity; thus in Case 215 the reticulocytes gave a "peak" of 19·4 per cent. on the ninth day, while the red blood-cells and hæmoglobin showed rapid increases.

Alcoholic filtrate from P5.—The combined alcoholic filtrates (A1–O1) were concentrated in vacuo at low temperature giving 164 g. of a yellowish-brown semi-solid mass, B5—representing 16 kg. of original fresh tissue. It was almost completely soluble in water, had no peptic activity, and contained 5·9 per cent. of total nitrogen. Of the reactions for proteins mentioned above only positive results were given with the Molisch, Folin phenol, Pauly, ninhydrin, and xanthoproteic tests. The usual protein precipitants, except phosphotungstic acid, likewise gave no precipitates.

This material (B5) was administered to two patients with pernicious anæmia in doses of 5 g. (equivalent to about 500 g. of fresh tissue) daily for 14 days without any responses.

Further fractionations of the solid P5 have been made, but have not yet been adequately examined clinically for their hæmopoietic activities.

CONCLUSIONS.

The experiments described in this paper appear to show that the active principles in liver and in hog's stomach effective in pernicious anæmia are not identical. The nature of the active principle in liver is, it is true, not finally settled, since West and Howe,[8] who first regarded it as a compound of β-hydroxyglutamic acid and γ-hydroxyproline, have now [9] withdrawn from their original position. Cohn and his co-workers [3] have, however, shown that the liver active principle is neither protein, lipoid, nor carbohydrate, but is either a nitrogenous base or a polypeptide. Our experiments render it highly probable that the active principle in hog's stomach effective in pernicious anæmia may be of an enzyme-like nature as has already been suggested,[2, 5] and consequently different from that present in liver. The evidence in favour of this conclusion can be summarised as follows:—

(*a*) We have been unable to extract the active principle from hog's stomach by methods which readily yield active extracts when applied to liver. This firmness of attachment of the active principle to the stomach tissue is in harmony with the readiness with which enzymes are adsorbed by proteins. It should be mentioned, however, that Gänsslen [10] has described the parenteral use of a preparation of stomach, but no details are available.

(*b*) The only method which has so far given an active stomach extract in our hands is the one which Büchner used to obtain the enzyme zymase from yeast—namely, expression of the juice from the cells by the application of great pressure.

(*c*) When the expressed stomach juice is treated with excess of alcohol a precipitate is obtained which is active in the treatment of pernicious anæmia. This precipitate, in common with desiccated hog's stomach and expressed juice, gives all the usual protein reactions. The alcohol filtrate from this precipitate, however, furnishes on concentration a solid which does not give many of the protein reactions, and is inactive in the treatment of pernicious anæmia. It appears probable that the active principle of stomach is either a protein-like material or else a substance which is associated with or easily adsorbed by proteins, such as an enzyme.

(*d*) Below about 45° C. most enzyme solutions are comparatively stable, but above this temperature inactivation soon commences, until at about 70–80° C. they are very rapidly destroyed. Now, according to Cohn, the active principle in liver is fairly stable towards heat, and even prolonged concentration of its solutions at 60° C. in vacuo does not destroy it. On the other hand, we find that active stomach preparations quickly lose their activities when heated above 45° C. The fact that the activity of stomach is much more easily impaired by heat than is the case with liver is in harmony with the hypothesis that the active principle in stomach effective in pernicious anæmia is of an "enzyme" nature.

(*c*) Castle[5] has demonstrated that the administration of the proteins of beef muscle, predigested in vitro with normal human gastric juice, induced remissions in cases of pernicious anæmia, though he was unable to get responses with gastric juice when given alone between meals in the absence of protein food.

One of us (J. F. W.), however, has shown that when normal human gastric juice is *given at meal times with protein food* to patients suffering from pernicious anæmia, a reticulocyte response does occur. This procedure was not followed by other workers when they failed to get responses with normal gastric juice.

In view of these facts and of the almost invariable association of pernicious anæmia with deficient enzyme secretion there seems to be good reason for believing that an important factor in pernicious anæmia is the failure of the stomach to secrete an essential substance of an enzyme-like character. This substance is neither pepsin, rennin, nor present in the intestinal juices, since they do not relieve the disease. It is not unreasonable to suppose that this unidentified substance acts on the protein present in a normal diet to produce the active "liver principle," which is most probably stored in the liver until it is required; it is not found in spleen, pancreas, intestine, or bone-marrow, and its presence in kidney may be due to an attempt to excrete any excess from the body.

For convenience we propose to apply the term "hæmopoietin" to this as yet unidentified active principle of hog's stomach; a more suitable name may be substituted if it is definitely proved to be an enzyme. Hæmopoietin may be identified with or allied to Castle's "intrinsic factor" of normal human gastric juice. The superior potency of stomach tissue may be readily accounted for by considering the presence of both (*a*) hæmopoietin, and (*b*) small quantities of the "liver principle" produced by the interaction (post mortem) of hæmopoietin on the stomach protein, which thus acts as the substrate or "extrinsic factor" of Castle.

If we are correct in our assumption that the active principle in hog's stomach is of the nature of an enzyme that can only act normally upon protein food introduced into the human stomach, it appears improbable that parenteral stomach preparations will be of much value; any potency that they may exhibit after parenteral injection being then due to the already formed active "liver principle." This would account for the results reported by Gänsslen who used intramuscular doses equivalent to 4 g. of mucosa—no details are given as to the preparation used, but the dose appears to be extremely small, and further reports on it are awaited with interest.

SUMMARY.

1. We have been unable to obtain stomach extracts that are hæmopoietically active for the treatment of pernicious anæmia by the usual methods which, when applied to liver, yield active extracts.

2. A method is described of obtaining active stomach extracts which involves the subjection of stomach tissue to high pressure in a special apparatus.

3. Experiments on the fractionation of this active extract have been described, and it is found that the use of alcohol readily separates a precipitate which is active in the treatment of pernicious anæmia whilst, on the other hand, the filtrate is inactive.

4. Further experiments on the concentration of this active fraction are in progress.

5. Some evidence showing that the active principle in hog's stomach is not identical with that present in liver is discussed.

6. It is considered that these experiments support the clinically suggested view that the active principle in hog's stomach effective in pernicious anæmia is of an enzyme-like nature. The suggestion is made that this "enzyme" acting on the proteins in a normal diet may produce a substance which is stored as the active principle in liver until it is required for hæmopoietic regeneration.

7. For convenience it is proposed temporarily to term this substance in hog's stomach "hæmopoietin."

We wish to acknowledge the valuable coöperation during the progress of these investigations of Prof. H. S. Raper, F.R.S., for his advice and criticisms; the honorary physicians and assistant clinical pathologists of the Manchester Royal Infirmary, and Dr. K. Bullock; Prof. Gibson and Mr. H. W. Baker, of the Department of Engineering of the University; and Mr. James Grier, for kindly allowing us to use the large-scale apparatus in the Pharmaceutical Department of the University.

Finally, we would thank the Medical Research Council, London, for a grant which has enabled one of us (L. K.) to take part in this work.

THE DIAGNOSIS OF DISEASES OF THE HIP-JOINT.*

BY JAMES F. BRAILSFORD, M.D. BIRM.,
HONORARY ASSISTANT RADIOLOGIST TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

FOR the past five years I have made a study of the patients sent for X ray examination of the hip-joint to the Royal Cripples Hospitals, the Warwickshire Orthopædic Hospital, the Queen's Hospital, the City of Birmingham infant welfare centres, the pensions hospitals, and to my own private practice. The earlier work was done in conjunction with that on lumbo-sacral deformities reported to the Medical Society of London in 1928.[1] The following is a list of the conditions met with.

In persons under 20.

Congenital dislocation of the hip-joint	88	Syphilis	4
Tubercle	60	Tumours	4
Perthes disease	33	Fracture of femur neck	3
Septic arthritis	27	Dislocation of hip-joint	3
Slipped epiphysis of femur	26	Myositis ossificans	3
Infantile coxa vara	15	Osteochondystrophy	3
Rachitic coxa vara	15	Cyst in femur neck	2
		Hæmophiliac changes	1

In persons over 20.

Osteo-arthritis	130	Secondary carcinoma	8
Chronic arthritis	73	Sarcoma	3
Septic arthritis	30	Cyst of femur neck	2
Fracture of femur neck	30	Syphilis	2
Paget's disease	12	Charcot's disease	1
Dislocation of hip-joint	10	Hydatid	1

CONCLUSIONS.

I have been led to draw the following conclusions.

Except in the case of acute disease, the diagnosis of hip-joint disease is almost entirely dependent upon end of the cylinder wall is provided with radial and circular grooves.

---

* Opening a discussion at the Medical Society of London on March 21st.

[1] See THE LANCET, 1928, ii., 1241.

(b) A base plate B of cast iron having a recess into which the cylinder is securely bolted. It is provided with an exit tube, E.2.

(c) An iron plate, L, perforated with very fine holes, and having radial and circular grooves cut out of its lower surface. These grooves and also those at the lower end of the cylinder C enable liquid to flow away easily. The plate L fits tightly in the lower end of the cylinder C.

(d) A steel piston P.

The finely minced fresh stomach tissue was thoroughly mixed with an equal weight of Calais sand, ground in a special mill to the correct consistency, and the soft "dough" then subjected to a pressure of approximately 2½–3 tons per square inch in the above apparatus until no further liquid could be obtained. Under these conditions we were able to collect good yields of the expressed juice; thus, for example, in a series of experiments the yield of juice was between 558 and 669 c.cm. per 1000 g. of fresh tissue.

Properties.—The expressed juice is a reddish, opalescent, rather viscid liquid containing a small amount of suspended matter which can be removed by filtration through cloth. It decomposes rapidly within 24 hours at ordinary temperatures, but keeps fairly well in a refrigerator for about five days.

The juice is distinctly acid towards litmus and has a pH of approximately 6·0. It coagulates with heat owing to the presence of proteins. It has a good pepsin content, but contains no rennin, amylase, lipase, or urease. The following protein tests were positive: biuret, Molisch, lead acetate sulphur test, Millon, Pauly, Adamkiewicz, p.-dimethylaminobenzaldehyde, ninhydrin, Sakaguchi, Folin phenol test, xanthoproteic. Precipitates were obtained with the usual protein precipitants (alcohol, acetone, phosphotungstic acid, picric acid, trichloracetic acid, metaphosphoric acid, tannic acid, and lead acetate).

This juice was shown to be very active in the treatment of pernicious anæmia in three cases after a daily dose of 150 c.cm. Thus in two cases the reticulocytes rose to 16·2 and 24·5 per cent. respectively on the ninth day after a preliminary control period of seven days; a third case showed an increase in reticulocytes, but the treatment was discontinued owing to nausea and other therapy was instituted.

CASE 206.—Maximum reticulocyte response, 16·2 per cent. on the ninth day of treatment. First day of treatment: red cells (R.B.C.), 1,700,000; hæmoglobin (Hb.), 46 per cent.; white cells (W.B.C.), 1800. Twenty-fifth day of *treatment*: *R.B.C., 3,250,000; Hb., 84 per cent.*; W.B.C., 5300.

CASE 207.—Maximum reticulocyte response, 24·5 per cent. on the ninth day of treatment. First day of treatment: R.B.C., 1,400,000; Hb., 36 per cent.; W.B.C., 3200. Thirty-fourth day of treatment: R.B.C., 3,600,000; Hb., 78 per cent.; W.B.C., 7600.

FRACTIONATION OF EXPRESSED JUICE.

The expressed juice described above having been proved active was subjected to further fractionation. Precipitation by adding 1 volume of juice to 5 volumes of 90 per cent. alcohol furnished a copious precipitate (P5) and an alcoholic filtrate; the usual yield of solid, P5, was 15–18 g. per 500 c.cm. of juice, 1 g. thus being derived from approximately 50 g. of fresh whole stomach tissue.

Properties of precipitate P5.—This light, cream-coloured powder was only partially soluble in water. The peptic activity showed that it contained approximately all the pepsin in the original expressed juice; rennin, amylase, urease, and lipase were absent. Nitrogen, phosphorus, traces of iron, calcium, and sodium were present, it contained 13·5 per cent. total nitrogen, and gave positive results with all the protein reagents mentioned above.

The administration of this powder to two cases of pernicious anæmia showed that it possessed considerable hæmopoietic activity; thus in Case 215 the reticulocytes gave a "peak" of 19·4 per cent. on the ninth day, while the red blood-cells and hæmoglobin showed rapid increases.

Alcoholic filtrate from P5.—The combined alcoholic filtrates (A1–O1) were concentrated in vacuo at low temperature giving 164 g. of a yellowish-brown semi-solid mass, B5—representing 16 kg. of original fresh tissue. It was almost completely soluble in water, had no peptic activity, and contained 5·9 per cent. of total nitrogen. Of the reactions for proteins mentioned above only positive results were given with the Molisch, Folin phenol, Pauly, ninhydrin, and xanthoproteic tests. The usual protein precipitants, except phosphotungstic acid, likewise gave no precipitates.

This material (B5) was administered to two patients with pernicious anæmia in doses of 5 g. (equivalent to about 500 g. of fresh tissue) daily for 14 days without any responses.

Further fractionations of the solid P5 have been made, but have not yet been adequately examined clinically for their hæmopoietic activities.

CONCLUSIONS.

The experiments described in this paper appear to show that the active principles in liver and in hog's stomach effective in pernicious anæmia are not identical. The nature of the active principle in liver is, it is true, not finally settled, since West and Howe,[8] who first regarded it as a compound of β-hydroxyglutamic acid and γ-hydroxyproline, have now [9] withdrawn from their original position. Cohn and his co-workers [3] have, however, shown that the liver active principle is neither protein, lipoid, nor carbohydrate, but is either a nitrogenous base or a polypeptide. Our experiments render it highly probable that the active principle in hog's stomach effective in pernicious anæmia may be of an enzyme-like nature as has already been suggested,[2, 5] and consequently different from that present in liver. The evidence in favour of this conclusion can be summarised as follows:—

(a) We have been unable to extract the active principle from hog's stomach by methods which readily yield active extracts when applied to liver. This firmness of attachment of the active principle to the stomach tissue is in harmony with the readiness with which enzymes are adsorbed by proteins. It should be mentioned, however, that Gänsslen [10] has described the parenteral use of a preparation of stomach, but no details are available.

(b) The only method which has so far given an active stomach extract in our hands is the one which Büchner used to obtain the enzyme zymase from yeast—namely, expression of the juice from the cells by the application of great pressure.

(c) When the expressed stomach juice is treated with excess of alcohol a precipitate is obtained which is active in the treatment of pernicious anæmia. This precipitate, in common with *desiccated hog's stomach and* expressed juice, gives all the usual protein reactions. The alcohol filtrate from this precipitate, however, furnishes on concentration a solid which does not give many of the protein reactions, and is inactive in the treatment of pernicious anæmia. It appears probable that the active principle of stomach is either a protein-like material or else a substance which is associated with or easily adsorbed by proteins, such as an enzyme.

(d) Below about 45° C. most enzyme solutions are comparatively stable, but above this temperature inactivation soon commences, until at about 70–80° C. they are very rapidly destroyed. Now, *according to Cohn*, the active principle in liver is fairly stable towards heat, and even prolonged concentration of its solutions at 60° C. in vacuo does not destroy it. On the other hand, we find that active stomach preparations quickly lose their activities when heated above 45° C. The fact that the activity of stomach is much more easily impaired by heat than is the case with liver is in harmony with the hypothesis that the active principle in stomach effective in pernicious anæmia is of an "enzyme" nature.

CLINICAL AND LABORATORY NOTES

ACUTE LYMPHATIC LEUKÆMIA WITH FACIAL DIPLEGIA AND DOUBLE ABDUCENS PALSY.

BY ALFRED HOWELL, M.D., M.R.C.P. LOND.,
MEDICAL OFFICER IN CHARGE OF THE DEPARTMENT FOR DISEASES OF CHILDREN, ROYAL INFIRMARY, CARDIFF;
AND
J. GOUGH, M.D. WALES,
ASSISTANT LECTURER IN PATHOLOGY, WELSH NATIONAL SCHOOL OF MEDICINE.

A BOY, 11 years of age, was admitted to the Royal Infirmary, Cardiff, under the care of one of us on May 12th, 1931. He had enjoyed good health until three weeks previously when, on his return from school, his mother noticed that his face was "disfigured" and that his speech was affected. There was no history of injury. He was put to bed, where he remained until he was admitted to hospital. Before being admitted his speech had improved a little. On one occasion he had suffered from double vision.

On admission to the hospital he was found to have bilateral facial palsy of the Bell type. The facial muscles showed no response to faradism. He had no difficulty in swallowing, his tongue had normal movement, and his somewhat "blunted" speech was due to weakness of the facial muscles. The sense of taste was normal. There was definite paresis of the right external rectus muscle not amounting to actual paralysis, but complete paralysis of the left external rectus. The optic discs were normal. A few hæmorrhages were seen near the temporal vessels in the right eye and a small one on the inner side of the disc in the left. There was no choroiditis. The knee- and ankle-jerks were feeble on the right and absent on the left side. The plantar reflexes were normal. The cervical, axillary, and inguinal glands were moderately enlarged. The spleen extended 2 in. below the costal margin. The liver extended 1 in. below the costal margin in the nipple line.

Blood examination: hæmoglobin, 55 per cent.: red cells, 2,950,000; white cells, 480,000, containing 93 per cent. of lymphocytes. The Wassermann reaction was positive. The blood-urea was 27 mg. per 100 c.cm.

The *urine* was normal.

Treatment and course of illness.—On June 4th 50 mg. of radium were applied in one focus over the spleen for 94 hours at a distance of 1·5 cm., a screen of 3 mm. of lead being used. The subsequent record of the white cell count is of interest.

June		June	
4th ..	Radium applied	10th ..	Leucocytes, 141,000
5th ..	Leucocytes, 712,000	15th ..	„ 428,000
6th ..	„ 500,000	19th ..	„ 544,000
7th ..	„ 252,000	25th ..	„ 414,000
8th ..	„ 106,000		

At this latest date the red cell count had fallen to 1,110,000. One week after admission the gums began to swell. They were purplish in colour and bled easily. The smell of the breath was very offensive. Petechiæ occurred for the first time two days before death and then rapidly appeared all over the body. The temperature chart showed a continuous pyrexia of 99° to 100°, not altered after the application of the radium. Death occurred on June 26th, six weeks after admission to hospital and nine weeks after the onset of the illness.

Post-mortem examination.—The body showed a moderate degree of emaciation. There were numerous petechial hæmorrhages over the front of the thorax and there was evidence of recent bleeding from the gums. Petechial hæmorrhages were also present beneath the epicardium, in the substance of the lungs, and in the mucosa of the stomach. These organs were otherwise normal. The liver weighed 1100 g. It was slightly enlarged, pale in colour, and friable in consistence. The spleen weighed 380 g. Its capsule was thickened and its substance was firm and somewhat pale except for an area of hæmorrhage at its upper pole. The Malpighian bodies were indistinct. The lymphatic glands throughout the body showed considerable enlargement, and particularly the anterior mediastinal glands, which formed a tumour-like mass in the region of the thymus. The kidney substance was pale but mottled with areas of hæmorrhage in the cortex. In the right frontal lobe of the brain there was a small circumscribed brownish area 3 mm. in diameter having the appearance of an old hæmorrhage. No other lesions were visible in the nervous system.

Microscopical examination.—The lymphatic glands, the spleen, the liver, and the kidneys showed the typical histological appearance of lymphatic leukæmia. The lymphoid infiltration of the kidneys was particularly severe, there being a diffuse involvement of the cortex and large circumscribed collections of lymphocytes in the medulla.

In the right frontal lobe of the brain the discoloured area consisted of a mass of lymphocytes intermingled with blood pigment. Throughout the cerebrum and basal ganglia were found several small areas of perivascular infiltration of lymphocytes. In the pons were found two very small lymphomas, one in the region of the main nucleus of the left sixth cranial nerve, and one involving the right nucleus of the trapezium. In addition there was recent thrombosis of a vessel running through the right facial nucleus. The nerve-cells of the sixth and seventh nuclei on both sides showed chromatolysis, shrinkage of the cell bodies, and margination of the cell nuclei.

Serial sections were made through the intracranial portions of the sixth and seventh cranial nerves. In these were found commencing degeneration of the nerve-fibres, associated with a very slight degree of leukæmic infiltration of the nerve sheaths.

Cerebral complications in leukæmia usually take the form of gross hæmorrhages or large areas of leukæmic infiltration in the cerebral hemispheres. These lesions are associated with suddenly developing paralysis or such symptoms as delirum, headache, and vertigo. Less commonly, local involvement of certain of the cranial nerves develops. Fried[1] cites 30 cases, all of which were examined post mortem. These he separated into three groups. The first consisted of 13 cases in which the hemispheres and meninges were affected by hæmorrhages and lymphomas. The second comprised seven cases associated with involvement of the cranial nerves, and the third was a group of 11 cases in which the spinal cord was implicated. In those of the second group the eighth nerve was affected in two cases and the facial nerve in five. Four of these five cases showed bilateral facial palsy. Other nerves affected in the cases in this second group were the fifth, ninth, tenth, eleventh, and twelfth.

In addition to those quoted by Fried we have found the following cases recorded. Laroche and Chatelin[2] reported a case of chronic lymphatic leukæmia in which facial palsy of the Bell type developed suddenly on one side, followed the next day by a similar palsy on the other side. This patient, a man of 64, after suffering from his diplegia for three months recovered after radiotherapy. Tromner and Wohlwill[3] recorded a case of lymphatic leukæmia in a woman of 55 in whom both facial nerves were involved, and the abducens muscles and the palate paralysed. She also had ptosis and difficulty in speaking, and her sense of taste was affected. They also record an interesting case of myeloid leukæmia in a man of 46 who suffered severe pain in the right cheek not relieved by the extraction of two teeth. In this case leukæmic infiltration of the fifth nerve-root was found. The infiltration was between the nerve bundles and did not appear to implicate the fibres themselves. Spargenberg[4] gave an account of a young man 17 years of age with facial diplegia and paralysis of the left sixth nerve associated with acute lymphatic leukæmia. Three weeks after the onset of the illness the left side of the face became paralysed; 18 days later the right side together with the left external rectus muscle became involved. No post-mortem examination was made. The distribution the radiograph. Even in acute disease radiography may supply very useful additional evidence.

A standard technique should be adopted for all radiographs of the hip-joint, otherwise faulty interpretation of the radiograph is almost bound to occur. The patient should lie on his back with the lower limbs stretched out with the feet symmetrically inverted. The tube should be centred vertically over a point midway between the anterior superior spine and the symphysis pubis. Both hip-joints should be included on the one film so that a comparison of density and uniformity of structure can be compared.

Certain irregularities of conformation of the hip-joint due to development should be recognised, including the os acetabuli, fovea capitis femoris, and the crenated upper border of the acetabulum.

Congenital subluxation is much less common than congenital dislocation.

Congenital dislocation is much more common in the female in whom the left hip-joint is most commonly affected. Radiographs permit of early recognition of the condition and show that early treatment secures the best anatomical results. Severe trauma during reduction often results in stunted development of the femoral epiphysis and neck. Changes similar to those seen in Perthes or Legg's disease of the femoral epiphysis are not uncommon after the trauma of reduction or attempted reduction.

Many causes of coxa vara are known, including trauma, localised osteochondritis (the so-called infantile coxa vara), slipped epiphysis, localised bone diseases (tubercle, Perthes, syphilis, osteomyelitis), generalised bone disease (rickets, osteomalacia, achondroplasia, chondro-osteodystrophy, cretinism, Paget's disease).

Fracture of the neck of the femur in children is not uncommon. It is relatively rare in early adult life, but its incidence increases with age. The fracture may not be detected in children until a coxa vara deformity has developed unless the child is radiographed at the time of the injury. About 50 per cent. of the fractures of the neck of the femur in adults and elderly people fail to unite.

Slipped epiphysis appears to be due to some disintegration of the metaphysis rather than direct trauma, as most of the patients with this condition give no history of trauma, and the radiographic appearances do not support the trauma theory. The epiphysis may be completely reduced, and the best result is a premature fusion of the epiphysis with a resulting ¼-inch shortening of the limb; often, however, the epiphysis undergoes degenerative changes.

The condition of infantile coxa vara presents a radiographic appearance suggesting fracture of the neck of the femur, and is sometimes diagnosed as such. The condition has an active and a healing phase. Osteotomy during the active phase may result in complete absorption of the disorganised bone of the femoral neck. The condition may be unilateral or bilateral. It may be [illegible] by radiographs during the first year of life. [illegible] appearances of rickets are quite distinctive and different from those of infantile coxa vara.

Perthes or Legg's disease frequently shows more extensive bone changes on the radiograph than the clinical signs would suggest. It has an active phase during which the bone is plastic and gives way to pressure, and permanent deformity may result because of this. It is usually about four years before the disorganised epiphysis is completely consolidated.

The radiograph may not show any bone changes in a patient suffering from early tuberculosis of the hip-joint, though the clinical signs may be prominent. The first signs may be a relative rarefaction of the bones around the joint. On the other hand, a radiograph may show definite evidence of tubercle when the clinical signs have not suggested tubercle. These apparent contradictions are due to the variation in the site and spread of the infection. All patients with clinical signs of hip-joint disease and normal radiographic appearances should be radiographed again after an interval. Radiographs will give a good indication of the cessation of the activity of the disease.

Syphilitic coxitis is frequently bilateral, its radiographic appearances are sometimes mistaken for tubercle or Perthes, but the appearances are distinctive, particularly if a series of radiographs of the hip-joints are taken throughout the course of the illness.

In active septic arthritis of the hip-joint dislocation is common, and in the majority of cases the head of the femur is separated as a sequestrum, or is destroyed by absorption.

Acute arthritis of gonococcal origin is often followed by a marked reduction of the joint space and irregularity of the articular surfaces, and, later, lipping of the articular margins.

Arthritis of the hip-joint *occurring* in the course of rheumatoid arthritis frequently results in the condition of protrusio acetabuli, due to pressure of the head of the femur on the softened bone of the acetabulum.

Following active septic arthritis latent septic foci may be left in the neighbouring bone, which may at a later date become activated and reinfect the joint.

The first radiographs of the osteo-arthritic hip-joint usually show extensive disease, diminution of the superior joint space, sclerosis of the approximated articular surfaces indicating destruction of the articular cartilage, and eburnation and erosion of the articular surfaces. Cyst-like degenerative changes in the bone, particularly in the superior articular surfaces. Joints showing these cyst-like cavities in the bone, indicative of early osteo-arthritis, but no diminution of the joint space do not cause the patient pain.

Following injury in the neighbourhood of the hip-joint it is not uncommon to see localised *myositis ossificans*.

After the reduction of a dislocation of the hip-joint the radiograph may show what appears to be a normal hip-joint, but marked new bone formation may be shown on subsequent radiographs. This is important in medico-legal cases.

Damage to the articular surfaces may not show for a long period after the injury.

Paget's disease (osteitis deformans) and secondary metastases of *carcinoma* may be shown on a radiograph taken because of a *fracture* or "*sciatica*" before the clinical evidence has suggested these conditions. The radiographic appearances of fracture in the two conditions are very distinctive.

A radiograph of the pelvis and hip-joints may reveal evidence of malignant disease in a patient suffering from an obscure illness.

Pain referred to the area of the knee-joint in children and adults may be explained by the evidence on a radiograph of the pelvis and hip-joints.

UNIVERSITY COLLEGE HOSPITAL.—The cost per occupied bed last year was £170. A good report is given of the antenatal and maternity work; during last year 90 per cent. of the mothers received an anæsthetic during labour without any ill-effect upon them or the children. Deep X ray therapy is being rapidly developed, and there is no scarcity of nurses.

that instead of pus we got pure liquid blood. Gas and oxygen anæsthesia was being adopted, as the patient would not allow even a puncture without it.

During handling of the mouth by the anæsthetist there was profuse bleeding, which was found to issue from the swollen, bluish gums. A history was obtained, after inquiry into diet, that the patient has not had green vegetables for last three years. A tight bandage was applied over the affected knee-joint, and six sour limes were ordered per day from the next morning. The improvement was so striking and remarkable that we were induced to increase the number to a dozen per day after a week. The patient's temperature became normal, he slept well, and his joint swelling vanished. At the end of a fortnight the remaining effusion of blood was got rid of by application of six leeches and Scott's dressing. At the end of three weeks the patient was out of bed, and his weight and general health have since improved considerably. He has been advised to take sour limes throughout the year.

Certain deductions can be drawn from the above case. (1) In acute or chronic arthritis with effusion the possibility of the presence of blood should be kept in mind. (2) In all joint affections, a routine examination of gums, an inquiry into the dietary of the patient, or of the occurrence of hæmorrhages elsewhere, would lead to greater accuracy in diagnosis. (3) Before freely incising any joint cavity an exploratory puncture in the operation theatre would help in the decision whether to operate or not.

MEDICAL SOCIETIES

MEDICAL SOCIETY OF LONDON.

AT a meeting of this society on March 21st, with Mr. HERBERT TILLEY, the President, in the chair, a discussion took place on the

Diagnosis of Diseases of the Hip-joint.

Dr. J. F. BRAILSFORD opened the discussion with a paper published on p. 721 of this issue.

Mr. D. MACRAE AITKEN said that clinical diagnosis ought to come before X ray diagnosis, because pain and symptoms would frequently be found before there had been time for such alterations in the bone texture as would show in the radiogram; symptoms and pain would also disappear long before the bone was cured. Mr. Aitken showed a number of radiograms relating to cases which he had followed right through from the onset of the disease or injury to the end. One case was a small boy who was brought up with recurring pain in the hip for seven months, and a diagnosis of tuberculosis. The essential point, however, was that although there was rarefaction of bone, there was a relative density of the head of the femur, and this appeared to contra-indicate tuberculosis, and the rarefaction was characteristic of that seen in Perthes' disease. The symptoms disappeared on treatment by recumbency, though some weakness still remained. In another child with a fragmented head, he decided that the head should not be allowed to bear weight, and therefore treated it in a double Thomas frame until he saw what he thought was full repair in that head. He showed by means of lantern slides the stages of the progress of the case over a period of three years, illustrating the slowness with which regeneration took place. The child had now a good round femur head, with no overlap to be seen. He disagreed with Dr. Brailsford in suggesting that slipped epiphysis was not the result of injury. His own opinion was that it was due to a twist injury in which the head remained in the acetabulum, the cartilage gave way, and the injured area became hyperæmic along the region of repair. He showed slides relating to a girl who had strained her hip at hockey, and had the same sort of pain as was found in the early stage of slipped epiphysis. He diagnosed the case as an attempt at slipped epiphysis, the girl being a little too old to have the actual condition. Mr. Aitken went on to remark on the operation introduced by Lavalle, of Buenos Aires, which consisted of tapping the hyperæmic area and putting in a thin spine of bone, so as to relieve congestion and promote bone repair. The success of this operation turned upon its ability to hasten the repair of the bone, and Mr. Aitken had definitely found that it did so. He had taken relapsed cases, in which the only course appeared to be to do an ankylosis, and in every case subjected to Lavalle's operation the pain and spasm had been relieved within a week. It was important, however, that the operation should take place into the hyperæmic area, and not into the caseous area. The operation had been adversely criticised by various authorities on the Continent, but Lavalle had insisted on the need for going into the hyperæmic areas, with the help of very good X ray pictures, and of avoiding the "cheesy" areas. Certainly in the cases which the speaker had seen the operation had been well justified, and he thought it a useful procedure for saving joints from destruction.

Mr. WHITCHURCH HOWELL said that in the child, in the case of tuberculous hip, opinion was veering round towards surgical treatment in some form. If he himself had a tuberculous hip-joint he would wish to have it ankylosed, but if he had arthritis of the hip he would wish to have some form of surgery done other than ankylosis, preferably some form of arthroplasty or, if that failed, arthrodesis. With regard to Lavalle's operation, he felt that this was only half tackling the problem, and that the surgeon ought to have more courage and undertake a real surgical approach to the hip-joint.

Mr. N. ST. J. BUXTON said that the cases for diagnosis of hip-joint conditions which were most difficult to him were the ones which resulted in a normal X ray picture. He mentioned the case of a schoolboy of 15 who was injured while playing football. He was told to lie up for a few days, and after about a fortnight went again into the football field, and his hip failed. The skiagram showed a normal appearance. After rest in bed for a fortnight or three weeks normal function was recovered. Of course, now and again one discovered tuberculosis in that way, but he took it that in the majority of these cases there was an effusion in the joint which, in the case of the knee, was visible because there the fluid was entirely superficial, but it was not seen in the case of the hip. When there was osteomyelitis in the upper part of the femur also the X ray picture was often normal.

Dr. BRAILSFORD, in replying on the discussion, admitted that in acute cases very often little help could be given by means of X rays, though at times information was forthcoming by that means which would not be possible by any other. With regard to the treatment of Perthes' disease, of which Mr. Aitken had shown so excellent an example, he noticed that in the last report of the American Orthopædic Association a remark was made to the effect that no good had come from rest treatment in this condition. But one had only to look at Mr. Aitken's examples to see that the condition could heal in the most wonderful way if treated properly.

of the paralysis was identical with that of the case we are now reporting, except that only one sixth nerve was affected in Spargenberg's case. One feature of special interest in his case was that a paralysis of one side of the face occurred while the leucocyte count was only 9000 with 76 per cent. lymphocytes, whereas later the white cells mounted to 151,000.

In those of the above cases where histological examination was made, the involvement of the cranial nerves was ascribed to leukæmic and hæmorrhagic infiltration of the nerve trunks. The present case, although corresponding clinically with the foregoing, differed pathologically in that the lesions involved the nuclei and not the nerve trunks. The lesions we found—namely, capillary thrombosis, perivascular accumulation of lymphocytes, and lymphomatous nodule formations—are, according to Fried, characteristic of intracranial changes in lymphatic leukæmia. Our case was unusual in that the pons was conspicuously affected.

A complicating feature in our case was the positive Wassermann reaction, since the possibility of the nervous lesions being syphilitic in origin had to be considered. Histologically, however, the lymphomas were characteristic of leukæmia, and apart from the perivascular infiltration of lymphocytes the vessel walls were free of lesions. No histological evidence of syphilis either in the brain or the meninges was found.

These cases make it evident that cranial nerve involvement in leukæmia may develop in a number of ways. Infiltrations and hæmorrhages may affect the nerves or their sheaths or the nerve nuclei. A case reported by Harris [5] suggests another possible occurrence. In his case symmetrical polyneuritis with symptoms of lymphatic leukæmia were found. He was of the opinion, on account of the symmetry, that the lesions were toxic in origin, in spite of the fact that he found the nerves infiltrated with lymphocytes. So far as the cranial nerves are concerned, however, pathological investigation would seem to show quite definitely that the lesions are due to leukæmic and hæmorrhagic infiltration rather than a toxin.

We wish to thank Dr. Leighton Davies for his report on the condition of the eyes in this case.

ADSORPTION OF IODINE BY ACTIVATED CARBON IN WATER TREATMENT.

BY B. A. ADAMS.

(From the Chemical Research Laboratory, Teddington, Middlesex.)

THE association of the iodine-content of a water-supply with the prevalence of endemic goitre has led to investigations of the effect of various purification processes on the iodine-content. Heymann [1] with the Amsterdam supply and Orr, Godden, and Dundas [2] with Aberdeen water have shown that only a small loss of iodine occurs as a result of filtration. Chlorination of London's water was found to have no effect on the iodine-content.[3] Softening by Clark's process (addition of lime followed by sedimentation of the precipitated calcium carbonate) however was observed to bring about a reduction of 50 per cent. of iodine in the Canterbury water.[4] Activated carbon is now being extensively employed for the removal of tastes and odours as well as for other purposes in water treatment and this substance is known to adsorb iodine and iodides from solution.

In order to study the effect of activated carbons, similar to those used in water treatment on aqueous solutions of iodine, two series of experiments were undertaken.

(*a*) Amounts of 3000 c.cm. of water containing 20 γ per litre (2 parts per 100 million) of iodine in the forms given below were passed through a 40 c.cm. bed of carbon contained in a glass tube (1·5 cm. diam.). (*b*) To 3000 c.cm. of similar solutions very finely divided carbon was added in an amount of approximately 0·5 parts per 100,000 and after stirring for a few minutes the solution was filtered through sand. Of the treated water 2000 c.cm. was taken for the determination of the iodine and the sodium nitrite process of Martindale and Westcott (loc. cit.) was usually employed, although certain modifications were necessary in some instances—namely, the addition of potassium nitrate prior to incineration to ensure the oxidation of the iodo-compounds in the presence of organic matter. The following forms of iodine were used: iodine, hydriodic acid, potassium iodide, potassium iodate, iodoform, iodophenol, and an infusion of the seaweed bladder-wrack (*Fucus vesiculosus*).

Both in distilled and tapwater (M.W.B. derived from the Thames) all these forms of iodine were removed invariably and completely by treatment with activated carbon either by passage through its granular form or by the addition of the powdered variety. The dissolved iodine is usually considered to exist in natural waters, either in the free state or as an iodide or iodate, but it probably sometimes occurs in organic combination.

Although it is desirable that an investigation on this subject should be carried out with a water-supply actually being treated with activated carbon before final conclusions can be drawn, these results show that certain forms of iodine are removed completely by such treatment. It is evident, therefore, that discrimination in the application of carbon in the treatment of water or replacement of iodine removed by the carbon may be desirable.

The author is indebted to Prof. G. T. Morgan, F.R.S., director of chemical research in the Department of Scientific and Industrial Research, for the interest taken in these experiments and for permission to publish the results.

SCORBUTIC HÆMARTHROSIS OF KNEE.

BY J. DURLABH DHRUV, F.R.C.S. ENG.,

SURGEON TO THE SIR JAMSHEDJI JIJIBHAI HOSPITAL, BOMBAY.

A HINDOO male patient, aged 32 years, sought advice at hospital because of inability to walk, and swelling of the right knee-joint. This joint had become swollen for a week without any injury.

He was extremely ill and was brought on a stretcher at the out-patient department. The knee-joint was hot, there was patellar tap, and the whole joint surface was very tender. He had had continuous fever for past six days, and a pulse-rate of 120 per minute, with a dirty tongue. There was thus a clear picture of a suppurative arthritis of knee. A colleague who happened to be present at the time agreed with me in this diagnosis. On exploratory puncture, before the operation, we found to our surprise fœtus, and the Aschheim-Zondek test was negative. She menstruated regularly for three months, and was then found to have a slightly irregular tumour reaching to a point two-thirds of the way to the umbilicus, and extending in the recto-vaginal space to within two inches of the perineum.

[4] Orr, Godden, and Dundas: Loc. cit.

Laparotomy revealed a pale, irregular, partly cystic tumour which was invading both broad ligaments and almost filling the pelvic cavity, a small area of the upper part of the uterus only being visible. Enucleation being impossible, the uterus was removed with the tumour, but the appendages were conserved. Histological examination of the tumour revealed a telangiectatic condition in places, and a collagenous stroma separating columns and strands of cells suggesting either an œdematous fibro-sarcoma, or an endothelioma, apparently arising in the cervix.

Mr. N. L. **Edwards** (Sheffield) showed two specimens of ovarian tumours resembling granulosa-cell cancer.

The first was removed from a married woman, aged 54, who was menstruating regularly, and had noticed an abdominal swelling with attacks of pain for several months. The tumour, roughly oval in shape, contained a cystic part near the lower pole and a solid area appearing like a scirrhous carcinoma, in the upper part. Section of the cystic part showed a typical cyst-adenoma, while the solid part of the tumour contained a dense stroma and also groups of epithelial cells arranged radially, many groups having a central clear space. In some of the central cavities there was a large cell containing much protoplasm, the whole picture suggesting an immature follicle and the consequent diagnosis of granulosa-cell cancer.

The second specimen was a large cyst weighing 17½ lb. removed from a patient aged 68. There was an irregularly lobulated solid mass the size of a coco-nut projecting from the main cyst. Section showed alveoli containing pseudo-mucin, and lined by several layers of high columnar cells resembling early carcinomatous change in a cyst-adenoma, but also certain solid groups of cells surrounding a central space which again suggested granulosa-cell cancer.

Mr. Edwards referred to Goodall's theory of the derivation of cyst-adenomata from the reticular cords, and to the possibility that, in the event of malignant changes taking place in one of these cysts, the cells might revert to a type bearing some similarity to those of the membrana granulosa.

THE LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.

A MEETING of this Association was held at B.M.A. House on March 17th with Dr. **Letitia Fairfield**, the President, in the chair. A symposium of four papers was read on

Analgesia and Anæsthesia in Normal Labour.

Dr. **Rhoda Adamson** (Leeds), speaking on the obstetrician's aspect, said that the objections voiced by the medical profession against the use of anæsthetics in midwifery cases came under three main heads, (*a*) the time that the medical attendant needed to spend with the patient, (*b*) the risk of post-partum hæmorrhage, (*c*) the risk of death from the administration of the anæsthetic. She pointed out that the obstetric art had changed from the province of the physician to that of the modern obstetric surgeon. At the present day, midwifery was considered to be always a department of surgery, and was only occasionally complicated by some medical condition such as a toxæmia or cardiac incompetence. The process of labour, if it was to be looked upon from the surgical point of view, could best be compared in the first and second stages to a colic, which was terminated by a spontaneous amputation at the placental attachment at the end of the third stage. Women who had experienced a spontaneous labour and a renal or biliary colic held that the pain was closely similar. Authentic cases of entirely painless labour had been observed, but they were undoubtedly very rare. Some observers denied the very existence of obstetric shock apart from faulty obstetric practice, but Dr. Adamson quoted cases where labour had been spontaneous, without any interference, and the patient suffered from severe shock. Want of rest and sleep during the first stage of labour led to exhaustion, and predisposed to shock; sedatives or narcotics were needed if the labour was prolonged. In the second stage of labour some form of anæsthetic helped to prevent laceration of the perineal body. If the pain was relieved, the patient was more amenable, and the scientific delivery of the child's head was achieved by the obstetrician only at the proper time. Dr. Adamson held that anæsthesia pushed to complete surgical degree at the time of the crowning and delivery of the head was the best aid to preventing tears. The objections raised to the giving of an anæsthetic in labour were then discussed. Many maternity nurses, from a desire to show their skill, welcomed the chance of a delivery before the advent of the doctor. This attitude in the maternity nurse was often encouraged by the family doctor unknown to the patient. The fee charged for a private maternity case in working- and middle-class practice was ludicrous in its disproportion to the demands upon the time and responsibility of the doctor. While such low fees were paid there was some justification for the point of view that midwifery takes up too much time from the busy general practitioner when he has other duties to perform. Dr. Adamson had found no evidence that the risk of post-partum hæmorrhage was increased by the use of a general anæsthetic.

In the Leeds Maternity Hospital it had been the practice since 1926 to administer a general anæsthetic to the obstetrical degree to all patients in exactly the same way as an administration would be given in an ideal private practice. This had been instituted for three main reasons: (1) humanitarian, to relieve suffering of the patient; (2) to teach the students the use of chloroform given by the drop method, since the anæsthetic of choice for general surgery is ether. It was also hoped that the students would learn to look upon an obstetric anæsthetic as the usual procedure, and that when they became family doctors they would use it on their patients; (3) the administration of a general anæsthetic made a deliberate delivery possible in every case, so that the stages could be demonstrated to every medical student and pupil midwife present at the labour. The anæsthetics were given in turn by students holding obstetric clerkships for three months, during which time they lived in a hostel beside the hospital, and were available for all deliveries during 24 hours every day. Anæsthetics were given for (1) examinations for estimating disproportion in contracted pelvis, and for certain versions, (2) all operative deliveries, (3) normal deliveries in every case of which the second stage lasted long enough for anæsthesia to be started. For examinations and version, open ether was given, and for operative deliveries the anæsthetic chosen depended on the type of operation—i.e., for a Cæsarean section usually ether, unless a spinal anæsthetic was preferred, and for a forceps delivery or perineal suture usually chloroform. In all normal deliveries chloroform was used after the presenting part began to dilate the vulvar orifice, and was continued until complete delivery of the head, delivery of the trunk and placenta being effected without any further anæsthesia while the patient was still somewhat under its influence. Open ether was used when the patient

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

At a recent meeting of this society held in Sheffield a paper on the

Conservative Treatment of Eclampsia

was read by Drs. E. A. Gerrard and R. L. Newton (Manchester). The 100 cases on which it was based had been collected during three and a half years, at St. Mary's Hospital, Manchester, and one or other of the authors had been partly responsible for every case. The paper began by reviewing the results of treatment during the 20 years from 1908 to 1928. Before 1920 there was no routine method of treatment, but this usually consisted of purgation and diaphoresis, while Cæsarean section and accouchement forcé were frequently resorted to. The mortality-rate for this period was 35·6 per cent. In 1920 the Dublin method was adopted, and as a result the mortality-rate fell to 19·8 per cent. for the following eight years. A criticism of this method was the adverse effect that repeated colon lavage appeared to exert upon the patient's heart. In 1928 a method was evolved which combined Stroganoff's method with certain eliminative measures. This method consisted of administration of morphia gr. ¼ and coramine (a camphor preparation) 1 c.cm. Half an hour later gastric lavage was performed, leaving in the stomach castor oil (2 oz.) and croton oil (2 minims); also colonic lavage was carried out, 2 oz. of magnesium sulphate being left in the colon. At 1½ hours, grs. 30 of chloral hydrate were administered by rectum or mouth; and the morphia repeated at 3 hours. The dose of coramine was repeated at the 4th, 8th, 12th, 16th, and 20th hours, and chloral hydrate grs. 30 was administered at 7 hours, while grs. 20 were given at 12 hours, and then eight-hourly if necessary. As a result of the advocacy by Schwarz and Dieckmann of the administration of intravenous glucose and intramuscular magnesium sulphate, the following additions were made to the standard treatment. At the commencement of treatment 10 c.cm. of 25 per cent. solution of magnesium sulphate were given intramuscularly, and 5 c.cm. after each convulsion, and at the same time dextrose was administered intravenously, 1000 c.cm. of 20 per cent. solution being employed, the injection being repeated if necessary.

There was no operative interference during labour, but in a certain number of cases induction of abortion or of labour was carried out on account of persistent albuminuria following recovery from eclampsia. The mode of delivery was by natural forces in 54 cases, by forceps in 17 cases, by induction followed by natural delivery in 7. There was spontaneous abortion in 8 cases, and induced abortion in 3 cases. Version followed by extraction, breech extraction, Cæsarean section, and craniotomy were each performed on one occasion, and 5 patients died undelivered. There were seven deaths in the 100 cases, and the mortality fell from 10 per cent. in 40 cases to 5 per cent. in 60 cases as a result of the introduction of dextrose and magnesium sulphate into the treatment. The fœtal mortality-rate, after excluding 18 cases of post-partum eclampsia and 11 abortions, was 57·7 per cent. This also included neonatal deaths. Only seven of the patients had attended the hospital clinic, and of these, three had not attended for some time, and all developed post-partum eclampsia. Two cases developed post-partum eclampsia after the commencement of eliminative treatment for albuminuria. In another case ante-partum eclampsia resulted within a few hours of eliminative treatment being started, and in the last case eclampsia followed labour induced for persistent albuminuria. Albumin was absent from the urine on admission in five cases and none of these patients died. The urine was clear in 78 of the cases on discharge from hospital.

In reply to questions raised during the discussion, Dr. Newton stated that the blood-pressure changes had afforded no help in the investigation. He only used chloroform during the preliminary washing out of stomach and colon in the presence of restlessness. The administration of glucose should be followed by polyuria, 200 g. being the maximum amount that it was safe to give, more being followed by glycosuria.

Accessory Ureter.

Dr. J. W. A. Hunter (Manchester) described a case of accessory ureter opening into the vagina.

The patient, whose age was 14, complained that in addition to normal micturition there was dribbling of urine for about an hour after the act, and intermittently at other times. There was incontinence of urine while she was asleep, and her mother stated that she had never been dry since infancy, in spite of many courses of treatment by drugs and training.

On examination the labia minora were markedly hypertrophied, and after insertion of a speculum a small opening, from which watery fluid exuded, was seen about half an inch above the urethral orifice slightly to the right of the middle line on the anterior vaginal wall. A probe passed for about two inches in a direction parallel to the urethra. The patient admitted to masturbation, and said that the irritation caused by the constant moisture had initiated this practice.

On investigation by cystoscopy after indigo-carmine injection two ureters were shown opening in normal positions, and each kidney apparently was functioning normally. Sodium iodide was injected into the suspected accessory ureter with some force, and radiological examination showed a track extending in a tortuous manner to the upper part of the right kidney. In conjunction with Mr. Hector Scotson, Dr. Hunter decided to explore the right kidney after a bougie had been passed along the right ureter as far as the renal pelvis. At operation normal kidney tissue was present with a large pelvis, but a small upper pelvis drained the upper pole of the kidney and led into a thickened tortuous and dilated tube, obviously the upper end of the accessory ureter. A wedge of the upper pole of the kidney with about six inches of the accessory ureter was excised. Convalescence was uneventful, the function of the right kidney was later shown to be normal, the patient is now in perfect health, and there has been a complete cessation of incontinence and masturbation.

Dr. Hunter had traced over 100 cases of accessory ureter opening externally, and mentioned several series of cases. He referred in particular to the theory advanced by Spitzer and Wallin in 1928, and confirmed by Kraft in 1931. This was to the effect that the so-called supernumerary kidney and ureter opening into the vagina is really a persistent mesonephros and Wolffian duct, thus distinguishing the condition from supernumerary ureters opening intravesically which result from bifurcation of the normal ureter. Dr. Hunter believed that his case afforded further proof of the theory. No indigo-carmine appeared at the accessory opening and there was no smell of urine and no evidence of irritation in the vulva or vagina. Also at operation the upper pole of the kidney was found to have a blood-supply quite distinct from the rest of the kidney.

Pelvic Tumours.

Prof. A. M. Claye (Leeds) described an unusual pelvic tumour removed from a patient, aged 29, who gave a history of two abortions and who was sent into hospital with a diagnosis of threatened abortion.

There was an enlarged uterus suggesting a retroverted gravid uterus, but X ray examination failed to show a

But the argument for sedatives and analgesia was chiefly that they would relieve the ordinary woman in her so-called normal confinement from severe and prolonged suffering which it was no longer necessary that she should bear. Dr. Phelps herself preferred, when the patient sent for her in good time, to give a sedative such as pot. brom., chloral hydrate with tinct. opii or an opium pill as soon as the pains began to cause discomfort. The sedative did not delay the labour ; it often seemed to expedite matters. The dangerous effect of opium on mother and child seemed to have been rather exaggerated, unless it was given in large and repeated doses. She withheld the anæsthetic until the head was upon the perineum, and gave it only for the last and most painful period of the labour. The difficulties could be met by a greater measure of coöperation between doctors and midwives in the management of pregnancy and labour. The delivery of the child might well be left in the hands of midwives, while the doctor who had been trained in the knowledge and use of potent and dangerous drugs should be responsible for the administration of sedatives and anæsthetics. It should be possible for all primiparæ, and all multiparæ who require it, to have the boon of sedatives and anæsthetics in childbirth. It was after all no new thing, and women in better economic circumstances had had it for years with no bad results. The time had gone by when one class, because of its poverty, should be debarred from the relief of prolonged and extreme pain.

THE MIDWIFE.

Miss Eva Pye (President of the Midwives' Institute) said that the fact that 60 per cent. of the births in this country were attended by midwives, and the theory that they were not fit to be trusted with any drug other than a simple aperient, had no doubt added its weight to the inertia on this question of the alleviation of pain in normal childbirth. The scantiness of the midwives' training in the use of drugs, the fact that local authorities discourage them from using drugs, and the acceptance among patients of the idea that nothing can be done to relieve pain, has led to midwives acquiescing in doing nothing to relieve quite unnecessary suffering. This attitude, said Miss Pye, was indefensible, being unscientific as well as heartless, and it might be one of the contributory causes of maternal morbidity, even mortality, through the exhausting effect of acute pain, and the debilitating effect of fear of it. In the first stage of labour, the use of sedatives was essential in some cases, and advisable in most, if not all. There was nothing in their rules to prevent midwives from making use of chloral, bromide, or even opium, provided they had been properly taught how and when to use them, or other suitable sedatives. Not a single case had been quoted in which the administration of sedative drugs by the midwife had proved harmful. It was not true that these drugs if harmless were also useless. The psychological aspect of the relief of pain and distress could best be observed by those who remained with the patient throughout her labour. The value of active treatment during the first stage with a firm promise of help for the final pains was of inestimable value. The midwife's practice was concerned with normal labour only, and as far as her experience was concerned she did not consider that for the second stage general anæsthesia was either necessary or advisable. She regarded it as an actual danger, in view of the temptation to the medical practitioner who alone could administer it, to interfere with the normal course of labour in order to shorten it, because of the pressure of his other work. There was, however, much to be said for being able to give the patient something to inhale during the later pains, and at their height, which would render the mother less sensitive. She had conceived the possibility of crushable capsules of chloroform, and these were now on the market. Thanks to the National Birthday Trust Fund the money had been found for the initial experiment of testing their value during the last nine months. Under Mr. Carnac Rivett the resident staff at Queen Charlotte's Hospital had tested them, and at the Middlesex Hospital the midwives had also tested them with complete success. From two to at most four capsules of 20 minims each appeared to give satisfactory relief, and there had been no contra-indication. Since the very small quantity of chloroform involved precludes true anæsthesia, and since an absolute check on any midwife using them would be available through her register in which the administration of each capsule would be entered, it was hoped that local authorities would not place any difficulties in the way. The use of such capsules would enable every mother in the country whose case was normal to have sufficient relief to take away the worst of the pain, together with the fear of it. Midwives wanted better training in the use of drugs that relieve pain in childbirth, and the free use of such drugs in training schools for midwives. As the attendants upon a normal function, midwives asked to be taught to remove as far as possible, fear, distress, and pain from every normal labour.

Mrs. Ivens Knowles said that she had always advised the use of morphia, although there had been a disinclination to allow midwives to give injections without the permission of the doctor in charge. Midwives should first be taught, and then authorised to give sedatives. She had never seen ill-effects from analgesia in the first stage. The administration of gas and oxygen was now taught to students. Would it not be better for them to learn simpler methods which could be used in practice ?

Mrs. Mallison asked whether there was any danger in allowing patients to use a Junker apparatus. Dr. Browne, in reply, thought that there was no danger to the mother because air was given with the chloroform, but a very long administration might have a bad effect on the child.

Dr. Dulcie Lukis said that when the patient has a severe pain she merely gripped the bulb hard and did not pump.

In answer to a question as to whether the few minims of chloroform had an actual analgesic action or worked mostly by suggestion, Dr. Adamson said that she had been asked to test some of the capsules spoken of by Miss Pye and had formed the impression that they were not so efficacious as chloroform by the drop method, but were much better than nothing. The difficulty would be to persuade local authorities that midwives should be allowed to use such capsules.

Dr. Katharine Lloyd Williams, who demonstrated a portable apparatus made by Messrs. King and Morgan, said that gas and oxygen was very simple to use and she could see nothing against allowing midwives to use it.

Dr. Remington Hobbs said that for many years at St. Mary Abbots Hospital no arrangement was made for analgesics in normal cases. Later morphia and a few whiffs of chloroform and ether were given and now gas and oxygen was the routine. He had already had chloroform, or suffered from toxæmia or organic heart disease.

Comparing results before and after 1926 when the general use of anæsthetics was instituted in her hospital, Dr. Adamson said that deliveries now were about 145 each month, against about 100 before 1926. The number of hæmorrhage cases and the number of cases of perineal laceration had lessened. No anæsthetic deaths had occurred. At present anæsthetics were not being given on district for normal cases. She considered that a discussion upon anæsthetics in obstetrics would be a matter for astonishment to the next generation for these reasons: (1) The mothers of the next generation would demand relief from the pain in childbirth as a rule, and would refuse to bear children if this was not conceded. (2) Obstetrics would come to be more and more looked upon as a branch of surgery involving the occurrence of a visceral colic, which led to great physical exhaustion, mental jolting, and surgical shock if unrelieved; on surgical grounds the use of anæsthesia would be considered an essential part of the scientific management of a maternity case.

THE ANÆSTHETIST'S STANDPOINT.

Dr. **Enid Browne** suggested that analgesia rather than anæsthesia was wanted, so that the mother could retain some consciousness of the hours of her delivery, while her pain was made tolerable. Three pains stood together as the most acute in character and exhausting in effect—biliary colic, renal colic, and the pain of a woman in labour. The two former were relieved as a matter of course; the latter thus far we had been content to watch because it was physiological in origin. At last there was an awakening to the real need of the woman in childbirth, which was not only that of safe delivery. Two main classes of drugs were available: drugs that could be taken by mouth, or injected, and inhalation anæsthetics. Injection could be rectal, intramuscular, intravenous, or spinal. Of rectal injections quin-ether and avertin had their indications, but only a small proportion of cases were suitable for rectal injection. Of intramuscular injections, morphia and its derivatives, especially opoidine and scopolamine, were discussed. With the latter each case needed careful watching. In some because the pulse became alarmingly rapid, or the patient might become maniacal. Of intravenous drugs, pernocton, sodium amytal, and nembutal were hypnotics, and when the amount necessary to produce deep hypnosis or analgesia was given, the drop in blood pressure might be alarming. Nembutal was now being tried at the London Hospital and at Queen Charlotte's. The pains were unaffected, but the patient had no memory of them. Spinal injections were very useful for the second stage in bad cardiac cases, but were limited in the time of action and not easy to give to one already in the throes of labour pains.

Inhalation anæsthetics.—Of these, ethylene had the disadvantage of being highly explosive; ether was also inflammable as well as being unpleasant to take and had also other disadvantages for routine use. C_2E_3 was a useful combination which might be more widely used in midwifery. Chloroform was of small bulk, potent and controllable in character. To the practitioner working single-handed it was invaluable, and the patient could safely be given a Junker to operate herself. It was the anæsthetic of choice if required for second stage or actual delivery of the head only. Dr. Browne enumerated the well-known disadvantages of chloroform, and pointed out that gas and oxygen was an anæsthetic that could be used from the beginning of the first stage to the end of the third stage if wanted, without harm to either mother or child. Its merits included depression of pain centres without loss of consciousness, absence of interference with the normal mechanism, a shortening of the second stage (because the patient's coöperation brings voluntary forces into play), and absence of shock and hæmorrhage. The difficulty of its universal use lay in its cost and its mechanical complexity. At present it was available only for the wealthy or the institutional patient. At the Royal Free Hospital, through a fund raised by Lord Buckmaster, Lady Balfour of Burleigh, and others, a resident anæsthetist was available for the service of normal labours. In the obstetrical unit under Prof. McIlroy, no woman who wished for alleviation of her pain need go without for want of an administrator. The unit statistics for the last six months' work, covering some 300 cases, would shortly be published. The general plan was to give sedatives either by mouth or intramuscularly during the first stage of labour, and gas and oxygen throughout the second stage, with either chloroform or ether for the crowning of the head. Experience had proved that if given at the right time (three fingers dilatation) morphia does not damp off the uterine pains. Given in the form of opoidine (1 c.cm. being equal to gr. 1/6 of morphia), it had had no harmful effect on any child. In the 300 cases there had been no case of P.P.H. attributable to analgesics. Even after a long labour, those who had received opoidine were alert and normal immediately after delivery. Miss Oldaker, the obstetrical anæsthetist, had informed the speaker that the whole of the cases had been anæsthetised during the second stage with gas and oxygen, except where they refused, or where the second stage was very rapid; the mothers described it as a godsend. Finally, Dr. Browne drew attention to a recent article by Prof. Hugo Sellheim, of the Frauen Klinik, Leipzig, appealing for the sanction of the profession for the administration of certain analgesics by midwives in the absence of the doctor. He pointed out how hard it must be for the midwives to listen to the "ceaseless complaining of the tormented woman" and have so little to offer her for her relief. Sixty per cent. of the women in England were delivered by midwives in their own homes; if our ideal was the alleviation of labour pains for every woman, we must pursue the quest for possible analgesics untiringly till we had found the maximum potency that could be given with absolute safety, not only by medical hands.

ANÆSTHETICS IN GENERAL PRACTICE.

Dr. C. **Phelps** said that it was necessary to remember what a simple thing an ordinary labour might be. She gave a graphic description of the difficulties which beset a doctor who attends a working-class woman in her home. A willing and conscious patient who would use and control her pains under the doctor's direction was usually easier to manage than a patient who was drowsy from drugs, light-headed and without self-control after light chloroform inhalation, or unconscious. Asepsis was more difficult to maintain when an anæsthetic had to be given or supervised by the accoucheur, while prolonged chloroform anæsthesia caused some lack of tonicity in the uterus, and sometimes a certain amount of hæmorrhage occurred when the placenta was separating. These difficulties were not insurmountable, and were mostly due to being single-handed. It was certain that the use of sedatives reduced the strain and exhaustion of a prolonged labour, while a timely anæsthetic might save a perineum from a troublesome tear.

But the argument for sedatives and analgesia was chiefly that they would relieve the ordinary woman in her so-called normal confinement from severe and prolonged suffering which it was no longer necessary that she should bear. Dr. Phelps herself preferred, when the patient sent for her in good time, to give a sedative such as pot. brom., chloral hydrate with tinct. opii or an opium pill as soon as the pains began to cause discomfort. The sedative did not delay the labour ; it often seemed to expedite matters. The dangerous effect of opium on mother and child seemed to have been rather exaggerated, unless it was given in large and repeated doses. She withheld the anæsthetic until the head was upon the perineum, and gave it only for the last and most painful period of the labour. The difficulties could be met by a greater measure of coöperation between doctors and midwives in the management of pregnancy and labour. The delivery of the child might well be left in the hands of midwives, while the doctor who had been trained in the knowledge and use of potent and dangerous drugs should be responsible for the administration of sedatives and anæsthetics. It should be possible for all primiparæ, and all multiparæ who require it, to have the boon of sedatives and anæsthetics in childbirth. It was after all no new thing, and women in better economic circumstances had had it for years with no bad results. The time had gone by when one class, because of its poverty, should be debarred from the relief of prolonged and extreme pain.

THE MIDWIFE.

Miss **Eva Pye** (President of the Midwives' Institute) said that the fact that 60 per cent. of the births in this country were attended by midwives, and the theory that they were not fit to be trusted with any drug other than a simple aperient, had no doubt added its weight to the inertia on this question of the alleviation of pain in normal childbirth. The scantiness of the midwives' training in the use of drugs, the fact that local authorities discourage them from using drugs, and the acceptance among patients of the idea that nothing can be done to relieve pain, has led to midwives acquiescing in doing nothing to relieve quite unnecessary suffering. This attitude, said Miss Pye, was indefensible, being unscientific as well as heartless, and it might be one of the contributory causes of maternal morbidity, even mortality, through the exhausting effect of acute pain, and the debilitating effect of fear of it. In the first stage of labour, the use of sedatives was essential in some cases, and advisable in most, if not all. There was nothing in their rules to prevent midwives from making use of chloral, bromide, or even opium, provided they had been properly taught how and when to use them, or other suitable sedatives. Not a single case had been quoted in which the administration of sedative drugs by the midwife had proved harmful. It was not true that these drugs if harmless were also useless. The psychological aspect of the relief of pain and distress could best be observed by those who remained with the patient throughout her labour. The value of active treatment during the first stage with a firm promise of help for the final pains was of inestimable value. The midwife's practice was concerned with normal labour only, and as far as her experience was concerned she did not consider that for the second stage general anæsthesia was either necessary or advisable. She regarded it as an actual danger, in view of the temptation to the medical practitioner who alone could administer it, to interfere with the normal course of labour in order to shorten it, because of the pressure of his other work. There was, however, much to be said for being able to give the patient something to inhale during the later pains, and at their height, which would render the mother less sensitive. She had conceived the possibility of crushable capsules of chloroform, and these were now on the market. Thanks to the National Birthday Trust Fund the money had been found for the initial experiment of testing their value during the last nine months. Under Mr. Carnac Rivett the resident staff at Queen Charlotte's Hospital had tested them, and at the Middlesex Hospital the midwives had also tested them with complete success. From two to at most four capsules of 20 minims each appeared to give satisfactory relief, and there had been no contra-indication. Since the very small quantity of chloroform involved precludes true anæsthesia, and since an absolute check on any midwife using them would be available through her register in which the administration of each capsule would be entered, it was hoped that local authorities would not place any difficulties in the way. The use of such capsules would enable every mother in the country whose case was normal to have sufficient relief to take away the worst of the pain, together with the fear of it. Midwives wanted better training in the use of drugs that relieve pain in childbirth, and the free use of such drugs in training schools for midwives. As the attendants upon a normal function, midwives asked to be taught to remove as far as possible, fear, distress, and pain from every normal labour.

Mrs. **Ivens Knowles** said that she had always advised the use of morphia, although there had been a disinclination to allow midwives to give injections without the permission of the doctor in charge. Midwives should first be taught, and then authorised to give sedatives. She had never seen ill-effects from analgesia in the first stage. The administration of gas and oxygen was now taught to students. Would it not be better for them to learn simpler methods which could be used in practice ?

Mrs. **Mallison** asked whether there was any danger in allowing patients to use a Junker apparatus. Dr. **Browne**, in reply, thought that there was no danger to the mother because air was given with the chloroform, but a very long administration might have a bad effect on the child.

Dr. **Dulcie Lukis** said that when the patient has a severe pain she merely gripped the bulb hard and did not pump.

In answer to a question as to whether the few minims of chloroform had an actual analgesic action or worked mostly by suggestion, Dr. **Adamson** said that she had been asked to test some of the capsules spoken of by Miss Pye and had formed the impression that they were not so efficacious as chloroform by the drop method, but were much better than nothing. The difficulty would be to persuade local authorities that midwives should be allowed to use such capsules.

Dr. **Katharine Lloyd Williams**, who demonstrated a portable apparatus made by Messrs. King and Morgan, said that gas and oxygen was very simple to use and she could see nothing against allowing midwives to use it.

Dr. **Remington Hobbs** said that for many years at St. Mary Abbots Hospital no arrangement was made for analgesics in normal cases. Later morphia and a few whiffs of chloroform and ether were given and now gas and oxygen was the routine. He agreed that more scope should be allowed to midwives, who should be allowed to give morphia or chloroform capsules.

Miss Margaret Basden laid stress on the mental factor. Women had great fear of the pain of labour.

Lady Barrett pointed out that even if gas and oxygen were relatively expensive the cost would be negligible as a national expenditure if midwives could be trained to use it, and it was such an extremely good anæsthetic that it could certainly not be left out of consideration. Research ought to be concentrated on an anæsthetic suitable for the large percentage of women delivered by midwives.

REVIEWS AND NOTICES OF BOOKS

Manual of Bacteriology.

Ninth edition. By Robert Muir, M.D., F.R.S., and the late James Ritchie, M.D., F.R.C.P. Edin. Revised by Carl H. Browning, M.D., D.P.H., F.R.S., Gardiner Professor of Bacteriology, University of Glasgow; and Thomas J. Mackie, M.D., D.P.H., Irvine Professor of Bacteriology, University of Edinburgh. London: Humphrey Milford, Oxford University Press. 1932. Pp. 866. 20s.

Our old friend, Muir and Ritchie, has reached its thirty-fifth birthday, having been revised, on an average, once in every four years during its life. Its format is the same as that in which it first saw the light but its slim figure has reached that portly habit which is so frequently the penalty of middle age. Prof. C. H. Browning and Prof. T. J. Mackie are responsible for the new edition which contains a considerable amount of new matter, especially in the section dealing with the viruses, whilst in other respects the book has undergone many modifications. The authors, wisely we think, have abandoned any attempt to provide a full bibliography and have contented themselves with giving references to the more important recent work and to classical papers; even so the bibliography occupies 35 pages.

The general characters of this book, which has so faithfully served the requirements of many generations of students and bacteriologists both at home and abroad, are so well known that it is unnecessary to restate them. Without being stimulating, or indeed even exactly pleasing to read, "Muir and Ritchie" has always been an accurate, wholly reliable, and competent work. It is remarkable how little information of value has escaped inclusion, which says a great deal for the care and judgment with which the material has been chosen. Almost the only point open to criticism that we have noted is that methods occupy as much as 120 pages—i.e., between one-sixth and one-seventh of the subject matter; in order to reduce this proportion, instruction on subjects such as section cutting and the use of the microtome might be left to the many excellent technical manuals or works on histology. It is curious that the old Sachs-Georgi should be the only flocculation test for syphilis described, for this test, though of historical interest, is nowadays not widely used. The illustrations are good and some of the photographic ones exceedingly good, but it is a pity that the publishers cannot include their colour plates in the text.

The Science of Signs and Symptoms.

By Robert John Stewart McDowall, D.Sc., Professor of Physiology, King's College, London. London: William Heinemann, Ltd. 1931. Pp. 440. 21s.

This book is an enlarged and altered edition, under an altered and perhaps less happy title, of the author's "Clinical Physiology," already well known in this country and abroad. Any rigid separation of physiology from the practice of medicine and surgery must ultimately be to the detriment of both, and attempts such as this one to bring the two into closer contact is welcome. Prof. McDowall will earn the thanks of practitioners who read his book, and his reward will be their added interest in the everyday signs and symptoms met with in the course of their work. For the contents will undoubtedly stimulate the reader to think—and perhaps argue—about many things which he has hitherto taken for granted or not bothered to inquire into. Its scope is large, and some parts of the subject are treated somewhat superficially. In places the meaning is difficult to follow. but for the most part the style is clear and emphatic, particularly in the chapters on the nervous system, respiration, and digestion.

We can heartily recommend the book as offering not only practical assistance in the understanding of disease but a stimulus to greater interest in physiological principles.

A Text-book of Pathology.

Fifteenth edition. By Francis Delafield, M.D., LL.D., and T. Mitchell Prudden, M.D., LL.D. Revised by Francis Carter Wood, M.D., Director of the Pathological Department, St. Luke's Hospital, New York; Director of the Institute of Cancer Research, Columbia University, New York. Edinburgh: E. and S. Livingstone. 1931. Pp. 1339. 55s.

This text-book of pathology, now in its fifteenth edition and sixtieth year, has never so far as we are able to ascertain achieved the same degree of popularity in this country as it has evidently enjoyed in America. It is a book written on conventional morphological lines, bearing some resemblance to Coats's pathology, which was familiar to students of a generation ago. In this edition there are still many survivals from an earlier stage in the evolution of pathology that might well have been omitted and many diffuse and indefinite statements which give rise to the suspicion that the author has not clarified his ideas upon the processes he describes. For example, the heading arterio-sclerosis (chronic arteritis) suffices for the whole gamut of conditions, such as atheroma, endarteritis obliterans, medial hypertrophy, Mönckeberg's sclerosis, and, apparently, syphilitic aortitis (since the Fig. 391, if it represents anything, shows syphilitic mesaortitis associated with a plaque of atheroma). To take one paragraph from this section of the book ". . . in the smaller vessels arterio-sclerosis may lead to extreme narrowing or occlusion of the lumen. When this does not occur, and especially in the medium-sized arteries, since the new tissue is less elastic than normal and liable to yield to the pressure of the blood, the lumen may in places be dilated (Fig. 392) or the wall may rupture.

In this way aneurysms may form." It is difficult to know what the student is intended to gather from this statement, or to reconcile it with what is known of the causation of aneurysm. Incidentally, Figs. 384 and 385 both bear the legend "Chronic arteritis—arterio-sclerosis—obliterating endarteritis," whereas in this country the one would be classified as atheroma and the other as endarteritis obliterans.

A similar lack of definition in the presentation confronts us when we turn to nephritis. Here we have nephritides (lesions in which inflammatory phenomena predominate) and nephroses (lesions in which the degenerative phenomena predominate), and yet under nephritides we find suppurative nephritis, acute diffuse nephritis, and chronic nephritis, the latter being subdivided into a vascular subgroup containing (*a*) arterio-sclerotic contracted kidney, and (*b*) a combined type or true contracted kidney, and a second subgroup of an inflammatory and degenerative type of chronic nephritis containing (*a*) a parenchymatous type of chronic nephritis, and (*b*) interstitial type of chronic nephritis. In the face of this galaxy of nephritides it is difficult to understand the reason for the existence of nephroses. These latter (we are told) are "lesions of the kidney in which the degenerative processes predominate." When we turn to these—after comprehending that the widespread web which embraces all the above-mentioned types of renal change has caught up only inflammatory conditions—we find that the histological changes in the nephroses may be considered under the heads of cloudy swelling, extensive cellular changes, reaction in the vascular connective tissue ("inflammation is evident in the interstitial tissue, and a few glomeruli may show a capsular hyperplasia and ultimately atrophy of the tuft"), and a stage of repair. And to add to this inferno of confusion amyloid change is also included under this heading. Of course, it is not wholly the authors' fault. They are in the best of company, and no doubt feel it incumbent upon them to find room for all views. It is the curse of renal pathology that it is still regarded as fair game for the systematist, whilst it exercises, for all claimants to any form of pathological knowledge, a fascination whose intensity is in inverse ratio to the experience possessed. No one suffers except the student, and even for him there is usually grace, for few examiners nowadays will risk a question in this most distressful subject.

Diabetes.

Its Control by the Individual and the State. Harvard Health Talks, No. 18. By ELLIOTT P. JOSLIN, M.D. London: Humphrey Milford, Oxford University Press. 1931. *Pp.* 70. 6*s*.

Diabetes mellitus is a disease which is increasing at the present time, and it now ranks ninth or tenth in the U.S.A. mortality tables. Little attention to the control of this disease is being given by individuals, and none by boards of health. Prof. Joslin, who has taught us much about diabetes, and has helped greatly to improve the treatment, is a most suitable person to give one of the Harvard Health Talks, presented as public lectures in the medical school, of which this is the eighteenth, to be published in volume form. The facts about diabetes and insulin, and the importance of diet, are given simply. The importance of the intelligent participation in the treatment by the patient or his attendants is stressed and a new way of spreading the gospel is described. "Wandering diabetic nurses" travel up and down the State of Massachusetts and visit patients in their homes; they advise about diet, and see that the doctor's instructions are being carried out. They work in collaboration with the local doctor, and help to spread up-to-date knowledge on diet and insulin. It is hoped at a later date to create diabetes centres in different parts of the State, where the doctor can send patients for estimations of blood-sugar, or send samples of their blood. At these centres a diabetic nurse will be available to advise about diets. The value of a well-trained dietetian, working in the out-patient department of a hospital is great, and Prof. Joslin's scheme is a good one, especially if the local doctors will coöperate.

He gives advice on the preventive aspect—namely, on the desirability of avoiding obesity, in order to maintain health and prevent the onset of diabetes. In his view two diabetics should not marry and have children, but the marriage of one diabetic, provided that the partner is aware of the dangers, is allowable.

Hydrogen Ions.

Their Determination and Importance in Pure and Industrial Chemistry. Second edition, revised and enlarged. By HUBERT T. S. BRITTON, D.Sc.Lond., B.Sc. Bristol, D.I.C., F.I.C., Lecturer in Physical Chemistry, University College of the South-West of England, Exeter. London: Chapman and Hall. 1932. Pp. 589. 25*s*.

SOME knowledge of the measurement and theory of hydrogen-ion concentration is nowadays an important part of many branches of science and industry, and in this book the author has succeeded in giving a straightforward account of hydrogen ions and their place in pure chemistry and in technical and industrial processes. The book is not merely a technical handbook. Its first half is concerned solely with the theory and practice of electrometric and colorimetric methods for the determination of hydrogen ions, and with the various types of half-elements and electrodes used in these measurements.

Some 50 pages are then devoted to the principles of volumetric analysis, including the nature of titration curves, with several examples showing the calculation from these of dissociation constants of acids and bases of various types. The dissociation of ampholytes and the "zwitterion" theory of Bjerrum are simply and clearly explained in this section. In the present edition this account is followed by a chapter giving a satisfactory introduction to recent theories of electrolytic solution, as far as they are involved in the study of the activity of hydrogen ions. The Debye-Hückel Lewis theory of electrolytes is accorded some 20 pages, and the biologically important question of the effect of salt concentration on dissociation of acids and bases is briefly discussed in the light of the activity theory. The author points out the difficulties in the way of defining electrode potentials in terms of activities of ions in view of the fact that no method exists for the determination of single ion activity. Throughout the book he adopts the policy of interpreting electrode potentials in terms of concentrations rather than of activities. In the present state of our knowledge of the theory of solutions, the tendency seems to be definitely in the direction of activities; but for most practical purposes it is not essential to make the distinction, and the idea of concentrations is probably still the more familiar one to the majority of readers. A comprehensive selection of buffer solutions is then described, including some useful "universal" buffer mixtures covering a very wide range of pH. Colorimetric methods of pH measurement have nearly 60 pages to themselves and this part of the book closes with full descriptions of the preparation of a number of indicator solutions for use in these methods.

The above occupies one-half of the total number of pages and constitutes a self-contained and concise, yet thorough, survey of the whole field. It is followed by the more special sections, of which five chapters are devoted to the importance of hydrogen-ion concentration in inorganic chemistry, more particularly in the precipitation of inorganic salts. It is in this field particularly that Dr. Britton has made many important contributions. The chapters dealing with the precipitation of phosphates and carbonates will be of special interest to medical readers.

The Mastery of Sex

Through Psychology and Religion. By LESLIE D. WEATHERHEAD, M.A. Assisted by Dr. MARION GREAVES. London: Student Christian Movement Press. 1931. Pp. 249. 5*s.*

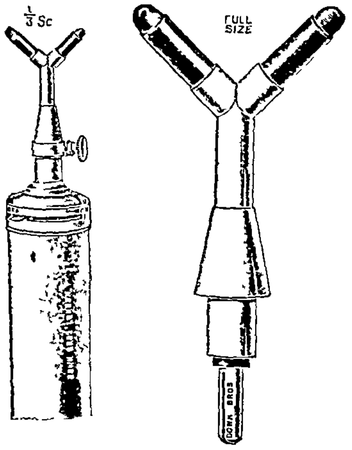
THE object of this book is to dispel the Victorian gloom and terror which has enveloped the problems of sex. Briefly, the thesis is to bring to bear upon the problems of sex such psychological discoveries, particularly in the field of psychopathology, as will help the layman to understand the sexual problems of adolescence and married life.

Mr. Weatherhead and Dr. Greaves do not, however, go the whole way on the road of psychological advancement; they pause to examine the psychological theories of sex in the light of current morality, and rest their views upon a broad Christian basis. The book deals with such human problems as silence and ignorance, comradeship and flirting, birth control, unhappy marriages, and the various disorders of sex life and the relationship of sex to society. The final chapter deals with healthy-mindedness, and the appendix with an outline of the physical facts, a knowledge of which is deemed necessary to happy marriage. While the book is full of interesting information and useful advice, one has the constant impression that while the author accepts the findings of modern psychology he feels under some restraint. He himself would probably be the last to admit this restraint on the grounds that the fundamental tenets of religion are prior to psychology and that all human actions must, in the final reduction, rest upon religious faith. The result is that there is a constant qualification of psychological opinion, and the book is in some danger of giving a false and faulty shelter to those who have the symptoms of a disordered sexual life.

NEW INVENTIONS

TEMPERATURE SENSATION TESTER.

THE instrument herewith illustrated consists of a plated metal piece, forked at one end to carry two special blackened electric lamps and a fitting at the other end to slip into the ordinary ophthalmoscope type of battery handle. One of the blackened lamps can be heated from the battery while the other remains cold. The heated surface is sufficiently large to give a definite area of fairly high temperature, while the contrast between the two—hot and cold—is readily appreciated. It is specially designed to be always available, easily carried inside the ophthalmoscope case, of no great weight nor size, and it is extremely valuable in just those cases where the more accurate determination of temperature sense is required.



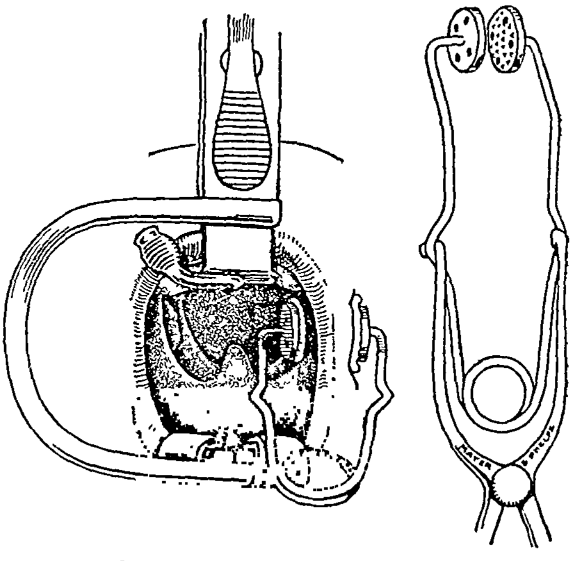
The makers are Messrs. Down Brothers, Ltd., St. Thomas's-street, London, S.E.

H. WOLFE CORNER, M.D.

Maida Vale Hospital, W.

A NEW TONSIL HÆMOSTAT.

THIS instrument consists of a simple spring clamp with end plates, to which swabs are attached. A special handle, or applicator, facilitates the use of the appliance (see Figure). In use several of the spring clamps with swabs attached should be sterilised with the dressings. The main difference between this hæmostat and others lies in the handle being detachable, while it is so designed that there is nothing to get in the way of further operative work in the throat. The pressure exerted is quite sufficient to control any "ordinary" hæmorrhage after the removal of the first tonsil. In this way time is saved, and unnecessary ligature of vessels avoided. The cost is inconsiderable compared with other more elaborate hæmostats.

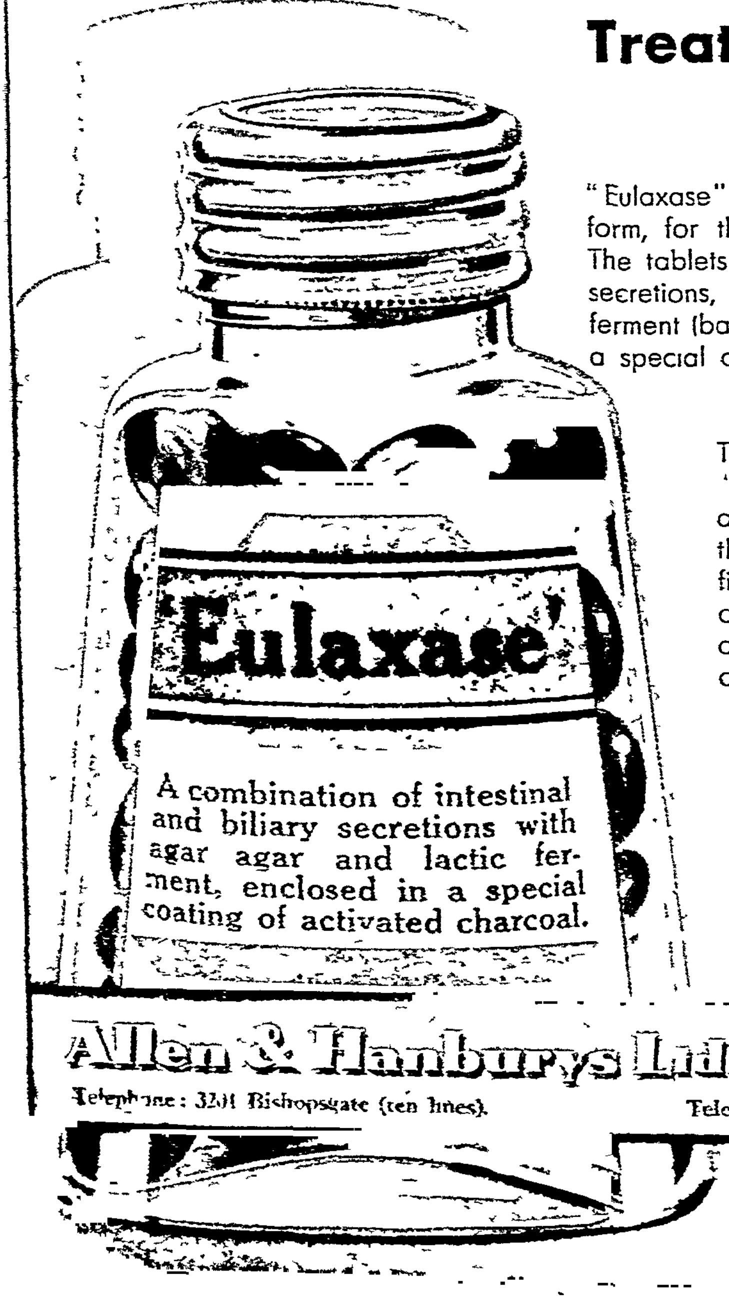


The instrument has been made from my design by Messrs. Mayer and Phelps, of 59–61, New Cavendish-street, W. 1.

Prescribe British

"EULAXASE"

For the Rational Treatment of Constipation



Eulaxase
A combination of intestinal and biliary secretions with agar agar and lactic ferment, enclosed in a special coating of activated charcoal.

"Eulaxase" is a new preparation, in tablet form, for the treatment of constipation. The tablets contain biliary and intestinal secretions, with agar agar and lactic ferment (bacillus acidophilus), enclosed in a special coating of activated charcoal.

The essential advantage of "Eulaxase" is that it provides a special substitute for each of the chief factors that are deficient in intestinal stasis. In other words, it forms a natural, complete, and efficient means of treatment for constipation.

In bottles of 60 tablets for prescribing, and 600 tablets for dispensing.

Descriptive leaflet and clinical trial sample will be sent on application

Allen & Hanburys Ltd., London, E.2

THE LANCET.

LONDON: SATURDAY, APRIL 2, 1932.

BRIGHTON'S HOSPITAL SERVICES.

THE British Medical Association recently complained of the inactivity of its branches and divisions in connexion with those local hospital services which were affected by the Local Government Act of 1929. Most of them, it was said, had failed to place the competent local authorities and voluntary hospitals consultative councils in possession of their views upon such matters as the best use of the existing council and voluntary hospital accommodation, whether additions to it are desirable, and what form those additions should take. Prominent among the three or four bodies exempted from this criticism was the Brighton division, which at an early date appointed a hospital committee to consider the whole subject. The proposals of the committee have now been adopted by the local medical profession and have been issued in pamphlet form for the consideration of expert and layman alike.[1]

The memorandum, which is a very thorough piece of work, is based upon the presumption that at all events in a great town like Brighton, with a high rateable value, the hospitals of the local authority will come into sharp competition with the voluntary institutions. In such communities the councils are able to obtain the best medical and surgical skill and to provide the newest and most costly equipment. If the voluntary hospitals are to retain their prestige, and to continue to offer an acceptable contribution to the public need, the committee believe that, while making the position of the visiting medical staffs financially attractive, they will be obliged to coöperate for the provision of the necessary equipment. This means that they must adjust themselves to new conditions which are hardly, as yet, in full working force. After a full review of the local circumstances, the main conclusion of the committee, accepted by the regional medical profession, is that the ultimate needs of Brighton, Hove, and the district would best be met by one general hospital, comprising all branches of medicine and surgery, and that this ideal should be impressed upon the governing bodies contemplating enlargement of their institutions. All fresh accommodation should be provided by building on sites provided at this general hospital, to which all the other hospitals in the district should be affiliated. Existing special hospitals should be either retained temporarily in their present form or used as recovery homes, for private patients, as local medical centres, or as "home hospitals," or any combination of these purposes or, if need be, sold. The medical centres would relieve the out-patient departments and allow of the continuation of the treatment of patients, on leaving the hospital, by their own doctor; the "home hospitals" would be for persons who, not necessarily on account of their means, were unfavourably situated as regards domestic accommodation in illness. It is cogently pointed out that the use of some of the existing hospitals as recovery homes would set free beds in the general hospital required for acute cases—at present in the Brighton district from ten days to three months are needed to remove a patient from the waiting-list. Thus, members of the visiting medical staff would retain their patients under their care until they could go to a convalescent home or were able to return home. The importance of these proposals is obvious. To retain a patient until he is entirely fit to be discharged from medical care may be a waste of beds, money, and energy; a stage comes, generally speaking, when both the patient and the hospital will benefit by his removal to a convalescent or recovery home. Another important recommendation is that when the time arrives for the creation of the proposed general hospital the county and county borough councils should coöperate in its formation. This is in accord with the suggestion of the memorandum on relations between voluntary hospitals and municipal hospitals, issued by King Edward's Fund, that where urgent needs are unsupplied the local authority should consider whether they can best be provided by the municipal or the voluntary hospital. The dominant notes of the memorandum are, indeed, the imperative need of concentrating the work of the voluntary hospitals and of friendly coöperation with the council institutions.

Any review of hospital work and needs at the present time must take serious account of the alarming and unmanageable increase in the number of out-patients, a growth often synonymous with abuse. The out-patient department is a necessary and valuable part of the hospital system, but what should be its primary object, consultation, has, in great measure, been lost sight of. The Brighton memorandum speaks with decision on the subject. Much of the work is said to be unnecessary and wasteful of money, professional time, and skill; and the existing checks are regarded as insufficient. The reforms suggested are comprehensive. Save in cases of emergency, access to the out-patient department should be obtained only by a recommendation from a private practitioner, a provident or other dispensary, a public clinic, or a public assistance medical officer. Only such treatment should be given as cannot, in the best interests of the patient, be obtained elsewhere under the usual arrangements as between doctor and patient, or under contract arrangement, and every case should be periodically reviewed. There is nothing here to limit the use of the out-patient department in cases where it is the obviously desirable resort, while the general practitioner would enjoy opportunities of consultation with the visiting staff which now are often hard to come by. There is much else of interest in a memorandum which, however closely it may come home to the medical profession, is also of concern to that wide public which at present is somewhat bewildered by changes vaguely understood and the implications of which are obscure. Its proposals are, indeed, avowedly submitted "to public bodies and public men and women interested in the subject." There will be differences of opinion, medical and lay, upon this or that recommendation the more especially since local circumstances vary, but, taken all round, it provides at least an interesting basis for argument and at best a foundation on which to build a coördinated hospital service that will eliminate wasteful overlapping and make the best use of skill and experience.

CONCERNING OLD AGE.

Some ten years ago Sir Humphry Rolleston delivered the Linacre lecture at St. John's College, Cambridge, taking as his subject the medical aspects of old age, and the lecture has now become, by some revision and much addition, a volume in which the accepted information on longevity is passed in review, while the ancient and modern aspects of the problems associated with advanced years are set out for comparison.[1] The medical treatment of the aged is not considered save in this indirect manner, that a valuable chapter deals with the causes of old age, and where we know causes the processes of treatment may become logical. On the other hand, we may find that the causes withstand all treatment, and this in the nature of things will be the usual situation with the subjects of old age. And no practical hints can be drawn from the records of those who have achieved remarkable longevity, because in the first place the records are remarkably untrustworthy, and, secondly, the best documented examples passed their extended lives in such extremely varying manner that they can have followed no common recipe for lengthening their days on earth.

In a recent study of the problems of human longevity,[2] Raymond Pearl, in conjunction with T. Raenkham, approaches the subject from the standpoint of constitution: what organ systems are most resistant to the wear and tear of living? There has been no dearth of discussion of the diseases of senility, from the time of Hippocrates onwards, but a review of the literature produces very little from the medical statistical aspect, although the material for such study is not lacking. In the U.S. registration area between 1923 and 1927 there were, out of a total of nearly six million deaths, 85,000 recorded as of persons 90 or more years of age at the time of their death. This is a statistical sample of respectable size, but its value depends largely upon the accuracy of death registration at these advanced ages. With the coloured population the statistics are very inadequate; a large proportion of their deaths at these ages (about one-third) are debited to "old age" and "senility"; the proportion is, however, much lower for the white population (about 13 per cent.), and for this reason the authors have confined their attention mainly to the latter. When the organological distribution of mortality in this group is compared with that of adults in other age-groups, it appears that the circulatory system more often than any other part of the body sets the upper limit of the human life span. The general conclusion is that if this upper limit is ever to be materially extended it will be necessary for man to acquire a circulatory system organically superior to the one he now has—though it might be argued that a more likely solution lies in the reduction of the strains to which it is subjected. The mortality associated with the respiratory system presents a somewhat different picture, for the *percentage* of the total deaths is not appreciably different at ages of 90 years and upwards from its level at ages 60 to 64 years. Passing beyond the individual causes of death the authors make a broad division of the organ systems into two classes: (1) those coming into direct contact with the external environment—e.g., respiratory system, sex organs, alimentary tract; (2) those not coming into direct contact with the external environment—e.g., circulatory system, nervous system. There appears to be a steady *decrease* with advancing adult age of the percentage of total mortality due to the causes in group (1)—i.e., those directly in contact with the external environment—and a correlative increase of the total mortality due to causes in group (2), those not in direct contact with the external environment. This at first sight is rather a surprising conclusion, possibly not in keeping with the results of investigations of a different type—such, for instance, as the negative correlation shown to exist between temperature and respiratory mortality, appreciable for old people but not for young adults, though, it is true, these correlations have not been worked for the very aged.

Common custom is certainly to protect the old from external environment. Whether the small percentage of deaths at advanced ages from causes in which the organs in close contact with the environment are involved, is the result of such protection or of the "survival of the fittest" is a question that these statistics cannot answer. Those who feel strongly that normal old age or senescence is connected with absorption of toxins from the alimentary canal will find in them some support of their views.

ORAL LESIONS AND THE DENTAL SURGEON.

The dental surgeon's preoccupation with the mouth puts him in a favourable position for observing lesions in that cavity in their early stage. He may often find himself consulted about complaints that are not dental in origin; or, on the other hand, he may easily see some condition, apparently trivial and quite unnoticed by the patient, which is none the less of grave significance. By tactfully suggesting the advisability of further examination, he may enable his patient to receive treatment at a time when it can still be useful.

[1] Medical Aspects of Old Age. By Sir Humphry Rolleston. London: Macmillan and Co., Ltd. 1932. Pp. 205. 7s. 6d.

[2] Raymond Pearl and T. Raenkham: Studies on Human Longevity. V. Constitutional Factors in Mortality at Advanced Ages. Human Biology. February, 1932, vol. iv., No. 1.

Prof. W. Rankin,[1] in a paper on Oral Lesions the Dental Surgeon may First Observe, writes of the importance of the dental surgeon being familiar with pathological conditions in the mouth beyond those which are due to diseases of the teeth, and points the moral by describing cases where such familiarity has been valuable. He emphasises the need for training in general medicine, and wisely remarks that the wards of the general hospital can alone provide such experience. His ideal that the dentist should be a physician who has taken up the practice of dentistry is, as he regretfully admits, an ideal which may be long in realisation. Indeed it might be argued with some force that if dentistry were strictly a specialty of medicine, to be learned after medical qualification, then the dentist might prove to be deficient in the technical skill required for the complicated operations of dentistry. The manual dexterity needed is very considerable, and the training should begin early and be continuous if real craftsmanship is to be acquired. Thus the conflicting claims of technique and of judgment based on a broad general training in medicine are not easy to reconcile. It is perhaps not surprising that those dentists who conform to Prof. Rankin's ideal of being physicians practising dentistry should sometimes be better in judgment than in execution, just as those who are primarily craftsmen may sometimes take a narrow view of their specialty. But leaving this contentious question, there will be few who will dissent from the general propositions which Prof. Rankin lays down. The dental student ought to know something of all oral conditions, whatever their causation; not with a view to treatment, but so that he may recognise their nature and inform the patient that medical attention should be sought. The dental surgeon who recognised Koplik's spots in a child on the verge of returning to school would earn the gratitude of the parent and the school authorities; he should also be able to distinguish mumps from the swelling due to an impacted wisdom tooth; while even more important, again, is the recognition of early cancer of the buccal cavity.

The curriculum of general medicine in the various licensing bodies which confer a qualification in dentistry is on the whole adequate. But a curriculum may look well on paper and yet the teaching may be poor, and if the examination is not sufficiently strict the candidate may slip through with a very scanty knowledge of medicine. Those who are in close touch with the dental student realise that that part of his training at a general hospital often leaves much to be desired. It is useless to let him loose with the medical student; his training in medicine and surgery should be carefully framed so as to present these subjects in relation to his life-work as a dentist. This means special classes so that he will not be unduly troubled with what later may be of little practical use to him. Economic reasons make it unlikely that more than a trifling fraction of dentists can qualify both in medicine and dentistry, for this means extending their studies for a further three or four years. Any limitation in the time devoted to purely dental subjects in favour of medicine and surgery carries with it too grave a risk of impaired technical ability to be possible. It is therefore necessary that the training in medicine should be carried out in a skilful and purposive fashion, and directed always to the aim of making the dentist not only familiar with, but even expert in, all matters connected with the mouth. In a word, his knowledge of pathology should be oral rather than dental. And this is essentially the message of a paper appearing in the March number of the Journal of the Association of American Medical Colleges, written by Dr. F. T. van Beuren. The author, who is dean of Columbia University College, New York, goes very thoroughly into the scope and the limitations of dentistry, and comes to the conclusion that "there is so much specialty and so little medicine about dentistry" that to regard the practice as a medical specialty, like ophthalmology or otolaryngology, is not justifiable. He obviously feels that the policy of perfection would be for every dentist to be a fully qualified medical practitioner, but that the perfection could only be obtained at the expense of time that could be occupied in a more practical manner.

THE RED CROSS RHEUMATISM CLINIC.

The staff of the British Red Cross Society's Clinic for Rheumatism have reason to be proud of the work they are doing. The second annual report is encouraging with its tale of doubled attendances and effective treatment, and it is satisfactory to hear that a greater proportion of the patients come for advice at an early stage. None the less the number of advanced cases is still unduly large, and, this being so, the medical board can fairly be pleased with the following percentage analysis of immediate results in 500 consecutive cases: worse, 0·8; unchanged, 22·6; slightly improved, 16·2; greatly improved, 46·6; and cured, 13·8. Evening clinics are held, and of 2475 patients discharged during the year 40 per cent. of the men and 51 per cent. of the women were able to remain at work while under treatment. The board's report concludes with notes on research already published or in prospect. It is all of interest, but much of it could be done more conveniently, one would think, with the patient in a hospital bed, ten of which are now in fact assigned to the clinic by the London County Council. Investigators must naturally follow their own bent, but it is frankly disappointing to find little mention at present of inquiry into the physiotherapeutic methods which could be studied at Peto-place much better than elsewhere.

ANNOTATIONS

THE DIPHTHERIA CARRIER.

ACTIVE immunity to diphtheria results either from naturally acquired infections with strains of the *Corynebacterium diphtheriæ* or by the injection of suitable preparations of the toxin which this organism produces. Although most of the infected attain natural immunity by means of subclinical infections, some purchase it only at the price of a hazardous experience—an attack of clinical diphtheria. Those who become immune either as the result of subclinical infections or a clinical attack may continue to harbour the parasite. They become "healthy" or convalescent carriers and may constitute a danger to non-immunes. Amongst immunes the carrier can do no harm. It is clear, therefore, that the rational method of control of diphtheria consists not in the hunting out of carriers of the diphtheria bacillus and their segregation until such time as they can be shown to have attained bacteriological righteousness, but in the increase in the proportion of immunes in the *population by means of artificial active immunisation.* In certain cities of the United States of America—e.g., Auburn and Utica—diphtheria has been almost completely eliminated as the result of immunising some 70 per cent. of the child population between the ages of 5 and 9, and at least 30 per cent. of those below 5 years of age (League of Nations C.H., 1053, 1931). Nowhere in this country have these figures been approached. Hence, the control of diphtheria still necessitates the control of the carrier.

Dr. V. D. Allison[1] has recently described some advances in the isolation of the diphtheria bacillus and modifications in the technique of the virulence test which together permit of rapid differentiation between virulent and avirulent strains. He employs Allison and Ayling's modification of Douglas's tellurite-serum agar, the modification consisting in the addition of 0·05 per cent. of copper sulphate. This medium inhibits the growth of the great majority of commensal organisms, and the *proteus* group. As a result, the diphtheria bacillus is readily obtained in pure culture. By the use of pure instead of field cultures for the performance of the intradermal guinea-pig test it is possible to report as to the virulence or otherwise of the strain in 48 hours. With the older methods, from seven to ten days might be necessary. Apart from economy in media and laboratory animals—Dr. Allison is able to dispense with the control animal—the saving of time is of very great importance to the medical officer who seeks to control an institutional outbreak of diphtheria by means of a combination of the Schick test and virulence test as described by C. C. Okell, A. J. Eagleton, and R. A. O'Brien.[2] Prompt detection and segregation of the Schick-negative or immune carrier of virulent organisms, the real danger in an institutional outbreak, is thus made possible. The carrier may harbour the bacillus in nose or throat or in both situations. The throat carrier is readily cured by tonsillectomy; the nasal carrier may be difficult to deal with. Drs. F. H. Thomson and Elsie Mann, together with Mr. Humphrey Marriner, record[3] further progress in an investigation into the diphtheria carrier problem which has been proceeding at the North Eastern Hospital since 1924. In the earlier stages of the investigation it was found that 7·5 per cent. of diphtheria patients persisted as carriers for *at least 12 weeks.* As the result of the intensive treatment adopted, the percentage of carriers has been reduced to 2·6 per cent., or a third of what it originally had been. It was recognised that the clearance of the nasal carrier was the great problem. Great success is reported with these cases from the use of 30 per cent. Dimol snuff. Six insufflations daily were prescribed. It is recorded that of 200 carriers treated by this method 76 per cent. required only one course of treatment and 60·7 per cent. of these became negative within a week and continued negative for six weeks, bi-weekly cultures being made. At the end of that period they were discharged from *hospital. In the same series of 200 carriers,* 6 *per cent.* required a second course of snuff treatment; 4 per cent. failed to be cured by the removal of tonsils and adenoids, but subsequently cleared up with snuff. A further 4 per cent. were cured by a combination of snuff and an alkaline nasal douche containing equal parts of the bicarbonate, biborate, and chloride of sodium. In 2 per cent. of cases the snuff treatment failed and clearance was effected by the removal of tonsils and adenoids. The carrier condition proved intractable in 7 per cent. of cases. In every instance it was found either that some marked pathological condition of the nose was present, such as ethmoiditis, deflected septum, atrophic rhinitis, or an infected antrum, or that the general health was poor from some other cause, such as tuberculosis.

As the result of the experience obtained in the treatment of carriers it was resolved by the authors to apply the same methods to the convalescent case of diphtheria, in order to obviate, as far as possible, the chronic carrier condition. To this end, every patient who was found still to be harbouring the diphtheria bacillus at the end of four weeks after an attack of the disease was examined by the rhinologist, Mr. Marriner, and appropriate treatment, either by operation, insufflations, or nasal douching, or a combination of these methods, carried out. That these methods were really efficacious in reducing the numbers of those who became 12-week carriers to a third of the original percentage of 7·5, was demonstrated by comparing a series of diphtheria convalescents thus treated with a parallel series to whom no special methods to effect bacteriological clearance were applied. As to the real value of swabbing and the number of negative swabs to be demanded before the release of a diphtheria patient from hospital, opinion is divided. There is no evidence that the diphtheria return case rate, usually in the region of about 1 per cent., is affected one way or the other by the performance or omission of an elaborate ritual of *swabbing before discharge. One reason for this is* the intermittency of the carrier state. A series of 12 or more negative swabbings may be followed by a positive result. Most diphtheria patients become bacteriologically free by the time that they are clinically fit for discharge, and it is customary to be content with two negative swabbings from nose and throat prior to release. The exceptional case continues to carry particularly in the nose, and it is satisfactory to learn from this prolonged and laborious investigation the best methods of effecting clearance in such cases. It is to be hoped that with the extension of the practice of active immunisation the carrier will become of less and less account. In any case, nobody should be classed as a carrier until the organisms he harbours have been submitted to a virulence test.

DIABETES AND PREGNANCY.

THE association of pregnancy with diabetes was formerly very dangerous. Thus before the introduction of insulin, Whitridge Williams collected 66 cases in 18 of which the patient died during pregnancy, labour, or the puerperium—a mortality of 27 per cent. Though an extra risk remains, because obstetric complications are necessarily more alarming in the diabetic, the outlook may be said to have changed completely now that insulin has become available. Numerous series of reported cases support this contention. In 1928 A. L. Walker collected 19 insulin-treated cases, of which only one proved fatal, and here the patient had suffered from severe toxæmia. In the same year in our own columns N. M. Goodman showed how the condition could be treated successfully under unpromising conditions in general practice. Last July, in a discussion at the Royal Society of Medicine, Dame Louise McIlroy and colleagues[1] at the Royal Free Hospital communicated seven cases, with eight pregnancies, in all of which delivery was natural, and in seven of which the child was alive and of normal size. Sterilisation was not performed on any of these patients, but Dr. E. W. Skipper,[2] who described 18 cases treated with insulin at the London Hospital, advocated sterilisation on account of the difficulty of prognosis. The decision, he would agree, is not one to be lightly made, and, as we pointed out on a former occasion,[3] the operation should be done only at the explicit request of the patient and her husband.

One of the latest papers on the subject appears in the *Norsk Magasin for Laegevidenskaben* for January, where Dr. C. Bruusgaard reports 12 cases observed at a maternity hospital in Oslo in the course of the last 25 years. The fact that the combination of diabetes and pregnancy occurred only in 12 out of 30,000 to 40,000 confinements in this hospital shows how rare it is. Only one of the patients belonged to the pre-insulin period, and this was the only case that ended fatally. The ages of the women ranged from 22 to 44, and five of them were primiparæ. Labour itself was on the whole normal, not being longer nor more often complicated by post-partum hæmorrhage than in the average case, and the puerperium also seemed to be unaffected by the diabetes. This series, like others, thus indicates that the risks of pregnancy are not particularly serious for the mother. But at Oslo the child mortality was high, for of the 17 pregnancies of these 12 diabetics, as many as eight terminated in the death of the child. Even in comparatively slight cases of diabetes, Bruusgaard says, the sudden intra-uterine death of the child is apt to take place without any apparent provocation. In the more severe cases, the chief danger to the child is acidosis and hypoglycæmia, whose control is none too easy. As a rule, in Bruusgaard's opinion, considerable difficulty will be experienced in deciding whether or not to interfere in the case of the diabetic woman, be she already pregnant or liable to become so. At his hospital several women were sterilised by operation, and the time recommended for this operation is on the fourth or fifth day of the puerperium, when the uterus is still large, and laparotomy under local anæsthesia is comparatively safe and easy. Mr. Eardley Holland, in the discussion previously mentioned,[2] maintained that Cæsarean section under local anæsthesia is the proper procedure unless labour is likely to be abnormally easy, and he suggested that when delivery is natural sterilisation might be performed some weeks later.

NERVOUS REGULATION OF BLOOD PRESSURE.

AN interesting communication on the tone of the blood-pressure regulator and its relation to the parasympathetic and sympathetic nervous systems comes from Prof. H. E. Hering of Cologne.[1] Since the discovery of the "sinus nerve" and the establishment of its function to be fundamentally the same as the "aorta nerve"—namely, controller of the blood pressure—Hering has been able to demonstrate that the tone of the parasympathetic is activated reflexly by the tone of the blood-pressure regulator. An intimate connexion is thus demonstrated between the sympathetic tone and the parasympathetic tone, the connecting link being the blood-pressure regulator. Many previous researches have shown that the tone of the sympathetic system is a true coefficient of the blood pressure; accordingly the sympathetic tone is also a coefficient of the parasympathetic tone by means of the blood pressure and the blood-pressure regulator; in other words, the blood-pressure regulator not only maintains parasympathetic tone, but inhibits the sympathetic. This circle must also have a fourth coefficient which remains yet to be discovered and must be the coefficient of sympathetic tone. Turning to the action of the sympathetic tone-producing mechanism on the organ which it innervates, it is found that, as regards the blood pressure, the action of the sympathetic is diminished by the blood-pressure regulator in two ways—namely, by auto-limitation and by stimulation of the parasympathetic tone—and as a result of this double apposition the normal resting tone is preserved. This is recognised experimentally when the blood-pressure regulator is cut out and the effect on the heart, vessels, and blood pressure is observed. According to Hering, on cutting out the blood-pressure regulator in the dog, the blood pressure rises steeply to twice the original level; therefore the double check must normally reduce the pressure to half its would-be level. By observation of the relation of the slowing of the pulse-rate to the rise of blood pressure during growth, it was found in the new-born, who have no vagus tone, that the relation of pressure to pulse-rate was roughly 60 to 120; with growth the pressure rose at first quickly and then slowly till at middle age the reverse was observed—i.e., a blood pressure of roughly 120 and a pulse-rate of 60. If the tone of the autonomic system, sympathetic and parasympathetic, at rest is described as the "resting tone," then this can be disturbed by any system of innervation—e.g., reflexly from an end-organ—one system being stimulated and the other inhibited; Hering says he knows of no reflex whereby the two forms of tone are stimulated simultaneously. Equilibrium is apparently restored by the "resting tone" after the disturbance produced by stimuli such as organ reflexes. The fact that the parasympathetic tone depends on the sympathetic shows the conception of both vagus and sympathetic in a new light; changes in degree of the normal sympathetic must involve changes in degree of the parasympathetic. Since, however, with changes in sympathetic tension the auto-check previously described comes into action, it is questionable how much of the tone remains latent when the blood-pressure regulator is in action, as described above in the experiment on dogs. In order to discover whether the resting tone of the autonomic system is of vital importance, experiments were carried out on dogs, and it was found that any sudden destruction of the blood-pressure regulator was fatal, whereas if the operation was carried out in several stages life could be maintained.

ROYAL INSTITUTE OF PUBLIC HEALTH.

THIS Institute, of which Sir William Smith was founder and remained Principal until his death on March 17th, will hold its annual conference over Whitsuntide at Belfast, under the Presidency of Lord Londonderry. It will meet on Tuesday, May 10th, and the work of the sections will begin next day. The Section of State Medicine, besides addresses and papers, is to have discussions on the vital factor in nutrition (opened by Dr. Chalmers Watson), the organised treatment of cripples (Miss M. Forrester-Brown), and venereal diseases as a public health problem (Dr. David Lees). In the Section of Industrial Medicine, Sir Thomas Oliver will introduce the subject of the health of the industrial worker, and there will be many personal communications. The two principal subjects before the Section of Women and Children are rheumatism (Dr. Robert Marshall and others), and the prevention of maternal and infant mortality (Dame Louise McIlroy). The Section of Tuberculosis will also hold two full-dress discussions, one on the place of the dispensary and the home in treatment (Dr. C. O. S. Blyth Brooke), and the other on tuberculosis settlements (Sir Pendrill Varrier-Jones). In the Section of Pathology Dr. C. O. Stallybrass introduces a discussion on problems of immunisation, and Prof. J. W. Bigger, with others, will contribute to a symposium on *Brucella abortus* infection in Ireland. The usual receptions and ceremonies will be held in connexion with the meeting. Apart from visits of instruction to places in the locality there will be pleasant opportunities of seeing some of the beauties and marvels of Northern Ireland.

HOG'S STOMACH IN PERNICIOUS ANÆMIA.

HÆMATOLOGY to-day is as much concerned with the physiology of the gastro-intestinal tract as with that of the hæmopoietic system. All observations therefore relating to the interaction of digestion and hæmopoiesis are of importance. Castle and his co-workers [1] have shown that a deficiency of gastric secretion is responsible for the development of a large group of megalocytic hyperchromic anæmias, while Wilkinson and Sturgis and Isaacs have corroborated these findings by showing that stomach preparations are as effective as liver in the treatment of such anæmias. Since the mucosa of the stomach or the muscle administered alone was ineffective it appeared probable that Castle's intrinsic factor was present in the mucosa, and reacted with the extrinsic factor in the muscle protein to form the effective principle.[2] In our present issue we publish further observations by Dr. Wilkinson and Mr. Klein on the nature of the effective principle in whole stomach and its relation to that in liver. They conclude that the two are not identical, since they were unable to obtain effective stomach extracts by the methods used in the case of liver. Those used in ex
tion of zymase from yeast proved satisfac

THE INCIDENCE AND SITUATION OF MYOCARDIAL INFARCTION.

A STUDY of cardiac infarction as seen in
consecutive necropsies has been made at the
Clinic by A. R. Barnes and R. G. Ball.[4] They
that when an infarct occurs in the left ventricl
it nearly always does, it usually occupies on
three situations, according to the distribution o
three main coronary branches which supply it
blood. One of these situations is the apex
anterior portion of the left ventricle and the ant
portion of the interventricular septum. Infa
here is due to the occlusion of the anterior descen
branch of the left coronary or more rarely of
main trunk, the infarcted area thus being some dist
from the site of the occlusion. The second com
site is the mid-portion of the ventricle in the re
of its left border, about midway between the
and base. Here the lesion is usually due to occl
of the circumflex branch of the left coronary.
third site, according to Barnes and Ball, is
overlooked. This is the posterior basal portio
the left ventricle, and the cause of the infar
occlusion of a branch, or of the main trunk, of the
coronary, or rarely of the left circumflex. In
1000 post-mortem examinations there was
evidence of infarction in about 5 per cent. A
majority of the patients were men, and a
70 per cent. of them were between 50 and 70 y
old. The figures given show that high blood pres
was by no means the rule in these patients; ne
theless cardiac hypertrophy was very com
though not invariable. Among 49 cases of infar
a definite occlusion of a main artery was foun
34, the anterior descending branch of the left coro
being involved most commonly. However, by ca
dissection in those cases where definite occlusion
not found, more or less complete obstruction of sm
vessels near the infarct was sometimes discove
the right coronary branches being slightly

often involved in this way than branches of the other main vessels. It is claimed therefore that the predominant rôle which tradition assigns to the anterior descending branch of the left coronary artery in the tragedy of coronary thrombosis is unwarranted, and that the right branch plays an almost equally important part. It is believed that the misconception arises out of the greater difficulty in dissecting adequately the tortuous right branches, and in opening them without dislodging a thrombus. Also it is asserted that infarction of the posterior wall of the ventricle will be found more often if this wall is carefully incised. The findings of these investigators, if confirmed, will destroy the claims of the anterior descending artery to be known as the "artery of sudden death," or "the artery of coronary occlusion."

MEDICAL TREATMENT OF CATARACT.

FROM time to time we hear of claims to restore the transparency of a partially opaque crystalline lens by means of medical as opposed to surgical treatment. The measures that have been advocated are, first, local application of a non-irritating nature—e.g., Dor's drops, containing compounds of iodine and calcium, and the calcium alkaline iodide ointment which had some vogue about eight years ago.[1] We hear little of this ointment now, and may conclude that it has not fulfilled the expectations that it at one time aroused. Secondly, there is the subconjunctival injections of some irritant such as cyanide of mercury with the object of causing hyperæmia of the ciliary body and so an alteration in the nutrition of the lens. Lieut-Colonel Henry Smith, of Indian fame, has long been an advocate of this treatment, which however is attended by pain so great that local anæsthesia is insufficient and morphia has to be used. In Smith's practice, nevertheless, a single subconjunctival injection of 20 minims of 1 in 5000 neutral cyanide of mercury is often sufficient to clear up an incipient opacity of the lens. But the loss of transparency thus overcome is not apparently associated with any definite opacities "beyond occasional black sand-like particles in the periphery in the early stages."[2] Without such definite opacities it is not usual to diagnose cataract at all.

Thirdly, there is the treatment advocated by Dr. A. E. Davis, of New York,[3] by injections of "lens antigen." The theory on which he works is that cataract is due to certain substances contained in the blood which are toxic to the lens alone (cataract patients are often quite healthy in all other respects). These toxins can be counteracted by the action of "antibodies" called forth by the injection into the system of a substance derived from the broken down lenses of animals—"lens antigen." The theory is so far plausible that it is widely admitted that the ordinary form of senile cataract is not a local disease but is probably dependent on some defect of general metabolism. Dr. Burdon Cooper, of Bath, who has for many years been working on the chemical changes involved in the cataractous process, is inclined to take this veiw.[4] In practice the treatment by daily subcutaneous injection is very prolonged and is apparently not without some risk of "anaphyllaxis" in case of intermission. On the other hand, according to Davis, the prospects of arrest or amelioration in early cases are good. Of 243 incipient subcapsular cataracts treated by him as many as 98, or 40 per cent., improved, and in an equal number of cases the process was arrested. To estimate the importance of these figures it would be necessary to compare them with untreated cases watched through equal periods of time.

Mr. W. S. Duke-Elder sums up the matter thus[5]:

> "It is true that in some early cases of acute cataract (true diabetic, traumatic), when the process has not progressed to actual coagulation of the proteins of the lens, transparency may be recovered by controlling the exciting conditions; it is also true that in all cataracts variations appear to occur due to changes in the fluid traffic and alterations in the refraction of the unstable lens; but it is as certainly true that an organic opacity once formed is immutable. Coagulation of protein is an irreversible chemical change."

It would perhaps shorten future controversy if the advocates of the medical treatment of cataract admit the soundness of the above dictum and if, on the other hand, their critics can give us a clinical test by which to distinguish those opacities which are merely temporary from those which are "organic." Meantime Mr. Duke-Elder's advice holds good, that while it is reasonable to attack and eliminate any exciting cause that is known or suspected, the only legitimate method of treatment is operative removal of the lens.

THE PSYCHIATRIC ASPECTS OF GASTRO-ENTEROLOGY.

OUR American colleagues give to the word "psychiatry" a wider significance than we do, as shown in an address to the American Gastro-Enterological Association by Dr. Adolf Meyer,[6] in which he discusses the relation between the part-function and the total-function of the patient as expressed in symptoms. Functional or structural stomach disturbance may result from local disorder, from the influence of other organ complexes, or from conditions of the personality functions. Thus arises the question of understanding what disturbances of the gastro-intestinal tract can be part of emotional states and topical experiences—mentally integrated processes calling for a knowledge of personality implications. Facts and situations are involved concerning which the student and physician should acquire as adequate training as about infections, poisons, and functional clashings or inhibitions, and Meyer believes that it is possible to understand the rôle of the so-called mental factor in the simpler and more easily managed conditions without going into problematic and protracted types of psychotherapeutic treatment. From his wide experience he is able to give practical advice to the physician on the elucidation of the patient's emotional difficulties. He gives a warning, for example, against precipitating antagonism by questions which the patient has to deny in order to save his face; one has to prepare the ground on which he can really find an incentive to seek aid, instead of blocking the way to further discussion. Here Meyer puts his finger upon the fact, already well known to those who are accustomed to investigate the mental difficulties of sick people, that some physicians have easy access to intimate histories that are a closed book to others. The physical examination of patients has been systematised so that the experience of ages is at the disposal of every student; on the other hand, the student or practitioner with the temperamental qualities that give insight into mental factors and facilitate their discovery has an initial advantage over his fellows which experience increases. Yet he would sometimes be tempted to yield up this advantage, for it carries with it the difficulty of conveying his findings to his colleagues or of having their significance recognised. Meyer's paper is an attempt to equalise matters and, in his own words, "to lead the physician who is almost exclusively taught to study parts of the organism and their functions to take an interest also in the total-function of the person."

FLORENCE NIGHTINGALE'S LATER WORK.

THE energy with which Florence Nightingale carried through her plans for the reform of nursing in the British Army is the chief theme of her latest biographer.[1] Those acquainted with the comparatively cloistered life of nurses to-day will find it interesting to be reminded how fiercely the founder of modern nursing strove against the restrictions of life in a Victorian home. "To be nailed to a continuation and exaggeration of my present life," she wrote, "without hope of another, would be intolerable to me." Her sense of frustration expressed itself in low spirits and irritability, and the consternation provoked by these symptoms has been depicted elsewhere by Mr. Lytton Strachey, in the imagined comment of her friends: "What could be the matter with dear Flo?" By dwelling on early obstacles Miss Willis is able to show how powerful was the driving force with which Florence Nightingale launched herself into the field of reform when once the barriers were down. She draws a character full of vigour, ruthless to herself and others in her determination to accomplish the task of the moment, and with a grasp of practical detail almost passionate. "I think what I have felt most," she wrote at one point, ". . . is the not having one single person to give me one inspiring word or even one correct fact,"—rather as though she might have dispensed with the inspiration. The book is a complete biography, and Miss Willis makes some attempt to analyse the human and religious motives which lay at the root of so much activity; her conclusions are interesting since they have a bearing on the vocational attitude towards nursing at the present time. She considers that in a religious age only a religious motive could justify a young woman in breaking away from custom. "God had to be brought into it," Miss Willis writes; "His call alone could justify such unusual conduct." But she regards Florence Nightingale as having been essentially a free thinker who brought in God, unconsciously, as a figurehead, "because the impulse to do this or that . . . came with such overpowering strength that she could think of no other source than God from whom it could have come." Many will be found to combat this view of her character, but it is one which provides ample grounds for speculation; the book is written clearly and concisely, and well documented. Miss Willis, in a foreword, confesses to owing much to Sir Edward Cook's biography of Florence Nightingale.

HYPERGLYCÆMIA AND SKIN DISEASES.

A PAPER[1] by Prof. G. Rost, of Freiburg, read at the last annual meeting of the British Association of Dermatology and Syphilology, should be studied by all interested in the inter-relations of metabolism and dermatology. The author has a concise and simple style, and the reader will have no difficulty in appreciating the points raised and the difficulties encountered, even if he be lacking in both biochemical and dermatological knowledge. The method described for administering glucose in estimating tolerance (i.e., intravenously instead of by mouth), and the reasons for so doing, will arouse general attention. Rost states that he never found hyperglycæmia in acne, seborrhœic eczema, furunculosis and other pyodermias, toxic dermatitis, carcinoma, or tuberculosis cutis. The same is true of eczema in a general sense, though he qualifies this observation by advising that a tolerance test should always be done where eczema does not respond to ordinary treatment. On the other hand, he urges that every patient with intertriginous dermatitis should be submitted to the test, and mentions that cases of psoriasis often exhibit a "pathoglycæmic" curve. Hypoglycæmia, which is probably an equally important abnormality, is not infrequently associated with so-called "flexural dermatitis," and in practice it is found that this common symptom, especially in children, diminishes with an increased carbohydrate administration.

While admitting that hyperglycæmia is a rarity in urticaria P. Chevalier[2] says he has tried insulin empirically in a case of apparently incurable chronic urticaria with excellent results. The patient, a woman of 32, had suffered from the disease for five years, the attacks seeming especially to follow ingestion of fatty foods. Five units of insulin (Byla) were given subcutaneously night and morning, with a little sugar simultaneously, and after a few days there was complete cessation of the pruritus, no matter what foods were allowed. A slight recurrence, after taking greasy foods, also cleared up when a second and similar series of insulin injections was prescribed. Another young woman, afflicted since childhood with the same disease, appears to have been cured in eight days, but she too was subject to minor remissions. It cannot be supposed that every case of chronic urticaria will respond favourably to insulin injections any more than we should hope that other opotherapeutic remedies, such as thyroid, recommended in the past, will always prove successful. It is well known too that whole blood, milk, and other protein complexes producing a greater or lesser degree of "protein shock" will sometimes relieve the symptom. Chevalier does not state that any of these had been used in the two cases he reports. We are therefore left in doubt about his claims, and only record the treatment for possible trial in intractable cases.

WE regret to announce the death on Monday last of Dr. George M. Robertson, the distinguished psychiatrist and physician-superintendent of Morningside.

WE also have to record the death of Mr. Rushton Parker, professor of surgery in the University of Liverpool.

MOORFIELDS EYE HOSPITAL.—This institution (the Royal London Ophthalmic Hospital, City-road, E.C.) reports a surplus on last year's working of £285, notwithstanding that the increase of beds since 1930 from 122 to 152 had sent up the expenditure by £6500. This increase has been met by augmented income, chiefly from legacies. During the year £16,537 was raised for rebuilding the out-patients' department, and King Edward's Fund has made an offer on behalf of an anonymous donor of a pound for every pound up to £6000 for the building fund provided that the hospital can raise an additional £6000 before next August.

EXTRA-CORPOREAL DEVELOPMENT OF HOOKWORMS.

By Clayton Lane, M.D. Lond.,
LIEUT.-COLONEL, I.M.S., RETD.

Seeing how high is the percentage of dwellers in the tropics which harbours hookworms and how great is the harm these parasites do, I have tried[*] to separate the factors which favour their extra-corporeal development.

The Need for Trapping Cultures.

The minimum, optimum, and maximum temperatures for this development have, I believe, been established since the observations of Lambinet and Bruns at the beginning of this century, some of the information indeed dating from Peroncito's work 20 years earlier. This belief is based on the fact that mere change in temperature can be imposed on eggs and larvæ *in conditions in which they remain* continuously visible. But when it is desired to determine certain of the physical conditions best suited for this development in nature, the opaque medium (soil or fæces) in which this is occurring precludes direct observation, and conclusions must be reached as inferences from the numbers of infective larvæ which are made visible both by being trapped as they escape from cultures and by being extracted by soakage from them.

Extraction has become a commonplace for all workers on hookworm infection, but the unescapable need to trap cultures (Lane, 1928), the extent to which larvæ may escape from them before extraction has been begun, has so generally escaped appreciation, and its implications have been so generally overlooked, that it is necessary again to stress its importance. In all cases considered below the number of eggs in the fæces used has been determined by D.C.F.F. (direct centrifugal floatation pushed to practical finality), using exactly 1 g. of fæces or an exactly obtained fraction of this if the number of eggs present made it advisable to do so. Seven days after setting for culture fæces containing 7668 eggs, 6370 emigrant infective larvæ were found trapped, and only 44 were then extracted. From another culture containing 10,230 eggs, 8130 larvæ emigrated and were trapped within seven days, and only 331 were then extracted. From two more, each containing 4880 eggs, 4740 larvæ escaped into the trap in one case and 2900 in the other, extraction then yielding 171 and exactly 600 respectively. From a fifth culture, containing 8300 eggs, 6890 larvæ had crept into the trap four days after the culture was prepared. Since extraction and extraction only has been the test used to determine the conditions in which development best occurs, its sole use in these instances would have held to be failures cultures which were *most successful; for a focus out* of which 144 of every 145 larvæ had migrated would have been reported as capable of doing little harm, whereas originally it had been most dangerous. As a contrast, in one of the cultures containing 4880 eggs, only 32 larvæ emigrated, and 463 remained to be extracted after seven days. Taking an average of 54 cultures which will shortly be considered, and in which the water content throughout varied within 10 per cent. only, 28·8 per cent. of the eggs set were accounted for as trapped larvæ, and 26·8 per cent. as extracted larvæ. In this relatively small series extraction missed more than half the larvæ which matured, while the individual differences of cultures have varied from almost complete emigration to complete failure to migrate. Migration has been the rule, and conclusions based on untrapped cultures which necessarily disregard migration have no exact value.

The Techniques.

CULTURE METHODS.

The culture methods have been fully described (Lane, 1928). Briefly, 4 g. of earth of a fixed texture and known water content were intimately mixed in a small Petri dish with 1 g. of fæces of known egg and water content, and a known quantity of water was added if desired. The water contents of earth and of fæces were taken as being shown by the loss of weight which occurred when the crucible containing them had stood for half an hour over a boiling water bath. All weighments and measurements were to within 0·01 g. or c.cm., and weighments were repeated at intervals to determine any change in water content. Each culture was trapped by being centred in a second rather larger Petri dish containing water, a clutch of three such trapped cultures was placed in a large water-containing Petri dish forming a common moat or trap, and this last was covered by an inverted Petri dish of the same size meeting it lip to lip and lined within on its flat surface with moist blotting paper. These covered clutches can be stacked above one another in an incubator, so saving space and expense, while in that case the wet and dry bulbs show that the atmosphere is almost saturated.

EFFICIENCY OF LARVAL TRAPS.

As measured by the number of larvæ found in the outer traps, the efficiency of the inner ones has in general been so great that escape from them has not always been tested. This was however done in 103 cases, and in them 806 of 47,998 larvæ which had migrated from the cultures (or 1·79 per cent.) were found in the outer traps. Since each outer trap normally captured escapes from three inner ones, it is not possible to say how many of these inner traps actually proved efficient; but taking those cases in which, while larvæ had entered the inner traps from the cultures, less than three had escaped from them into the outer one, not less than 67 of 103 traps were fully effective. In only two did the numbers of larvæ exceed the average, indicating that it was these two which made the average as high as it was. In view of this general efficiency it seems unreasonable not to seek in individual traps an explanation of their failure. Evidence of this became apparent only towards the end of the investigation. Thirteen larvæ lay at the top of a wisp of submerged cotton fibrils in a trap which contained 744 of them; the water in the trap, which had stood undisturbed for 40 days, was rather low; there were 29 larvæ in the outer trap. It seems fair to conclude that escape from a trap may be possible if larvæ can obtain a ladder to the surface and purchase to perforate the surface against its tension, and that in this case ascent took place from one fibril to another. Moreover, the metal stays which were designed to prevent larvæ from obtaining climbing and perforating purchase in full traps may well provide it when the surface level falls. Whatever may be the explanation of the unexpected finding of Africa (1931) that the corresponding stage of the rat strongyle, *Nippostrongylus muris*, can emerge on the outer wall of a water trap 5 cm. wide and 2 cm. deep, the conclusion formed after long watching of hookworm larvæ in an examination cell seems to preclude absolutely the possibility of their escape from a depth of clean water greater than their length of 0·6 mm. They have never been found in the inverted Petri dish which serves to cover the clutch of cultures.

---

[*] The investigation occupied about four years until closed by ill-health. The work was done under grants renewed annually by the Royal Society and was carried out at the Royal Albert Dock Hospital by kind permission of the Seamen's Hospital Society, in a laboratory generously vacated by Dr. H. M. Hanschell, and on material courteously made available by the hospital staff and particularly by Drs. G. Carmichael Low and P. Manson-Bahr.

METHODS OF EXTRACTING LARVÆ.

As is well known all extraction methods are modifications of that of Looss (1911), who placed the material to be tested in a calico bag, hung this in water, and pipetted off the escaped larvæ after they had fallen to the bottom of the vessel. Baermann (1917) set the calico in a metal sieve standing in a water-filled funnel, and by later opening the pinchcock beneath drew off the larvæ which had fallen to the bottom. Cort et al. (1922) modified Baermann's method by using the water hot and by not completely submerging the material to be extracted. The writer (Lane, 1928) placed the small culture already mentioned within calico-lined wire gauze moulded inside a small Petri dish, filled this with water and stacked covered clutches of these within an incubator or on the bench. This procedure has the advantage of allowing many extractions to be carried out at the same time in an incubator at a fixed temperature. Since the procedure has these marked advantages of convenience a comparison of its effectiveness with that of Baermann is necessary.

RELATIVE EFFECTIVENESS OF BAERMANN'S AND LANE'S EXTRACTION METHODS.

Cort (1925) reported that in a considerable series of experiments his modification of Baermann's apparatus extracted between 50 and 60 per cent. of larvæ which had been added to a clay loam. Perhaps these figures mean averages. At all events they do not apply to all soils, since Hirst (1924) had already shown that efficiency of extraction by Baermann's apparatus varied with the nature of the soil. Thus, 3·4 to 20 per cent. of infective hookworm larvæ added to a soil from a laterite formation made up of ferruginous sand and clay were later extracted. The percentage extracted from fine sand was from 4 to 20, and from a gravelly loam containing much humus 82·5 to 84.

In the present investigation the matter was considered differently. Twenty-four of the cultures described were divided by eye into seemingly equal halves, and one half of each culture was extracted by Baermann's method and the other half by mine. The two tests were conducted side by side on the bench, since the Baermann apparatus was too big for the incubator; the temperature of the room lay between 45° F. and 63° F. From their respective half cultures my technique extracted a total of 3707 larvæ and Baermann's one of 2985. Such a method of comparison gives, however, undue weight to any heavily infected culture in which one technique has happened to produce better results than the other. The fairer method is to determine the percentage of the whole extraction which each method has effected from its own half of each culture. From these 24 halved cultures my extraction method collected an average of 55·3 per cent. and Baermann's 47·7 per cent. of the total recovery of larvæ. It was further found that in Baermann's method all larvæ were not necessarily collected by running out of the funnel the 16 c.cm. which filled the glass box used for examination. Emptying the funnel has added as much as a twelfth more, and it is not suggested that this is a maximum. Moreover, the impression has been gained that to tap on the funnel before opening the stopcock has lessened the likelihood of leaving larvæ behind. Presumably it activates them so that, as they wriggle, they slip down the walls. It will have been noted that the division, although apparently equal, was relatively roughly come by, and that the number of cultures was not great, but that neither technique showed a preponderatingly large total; so that the choice between the two may reasonably be held to depend on local convenience, particularly as this is affected by temperature and space. The present significance of this comparison lies in the fact that the writer's technique was used in all that follows, and that it is at least as reliable a means of extraction as is Baermann's.

RETARDED EXTRACTION OF LARVÆ.

Although it seems to be the invariable custom to carry on extraction for a few hours only, infective larvæ may in fact continue to be recovered for many days after cultures have been set for extraction as the following instances show. From a culture 54 days old which had contained 10,230 hookworm eggs, 851 infective larvæ were recovered within 24 hours of setting it for extraction, 269 larvæ between the second and ninth days, 3 in the next 24 hours, and 3 between the fiftieth and fifty-ninth days. From another culture extracts were still successful 45 days after extraction began. From a third, set for extraction when nine days old, the numbers of larvæ so recovered were 330 within 24 hours, 136 between two and four days, 8 between five and 19 days, and one between 20 and 29 days; extraction for 24 hours has revealed three-quarters or less of the total recovery. For this retardation two explanations seem possible: either development of all eggs is not simultaneous in such cultures, or infective larvæ may be imprisoned by some local condition when the culture is set in water for extraction. That in the depths of a large fæcal mass development was suspended, evidently from lack of oxygen, was shown by Looss (1911); but this explanation has little to support it in the case of shallow unsodden mixtures of earth and fæces, for air must readily penetrate them in consequence of the time and care taken in their preliminary mixing. This conclusion is strengthened by the high percentage of larvæ which may reach the infective stage and emigrate even within four days—as many as 83 per cent. of all eggs being so accounted for in an instance already quoted. Again, in setting cultures for extraction it has frequently happened that small particles have floated and could not be submerged even after crushing them with fine forceps, a condition evidently due to retention within them of some gas; and as long as this float has persisted it has been found that a few larvæ might continue to be extracted. It seems a requisite of complete extraction that water should extend through the whole mass, and this cannot be guaranteed unless there is complete submersion.

Temperature too may be important in extraction, as Cort and his colleagues held (1922). For instance, no larvæ left two cultures 24 hours old while they stood on the bench for extraction at a temperature between

4° C. and 16° C. After adding water at 38° C. and replacing them on the bench, 24 and 22 larvæ had been extracted at the next examination three days later. It seems fair to conclude that the increased activity which is brought about by heat enables larvæ to break away from restraining agents, or expands and expels retained gas which has been imprisoning them. Accordingly extraction was not subsequently considered complete unless cultures had been exposed in an incubator to a heat of 28° to 30° C., and attempts at obtaining complete submersion had succeeded.

Physical Conditions Best Suited for Development.

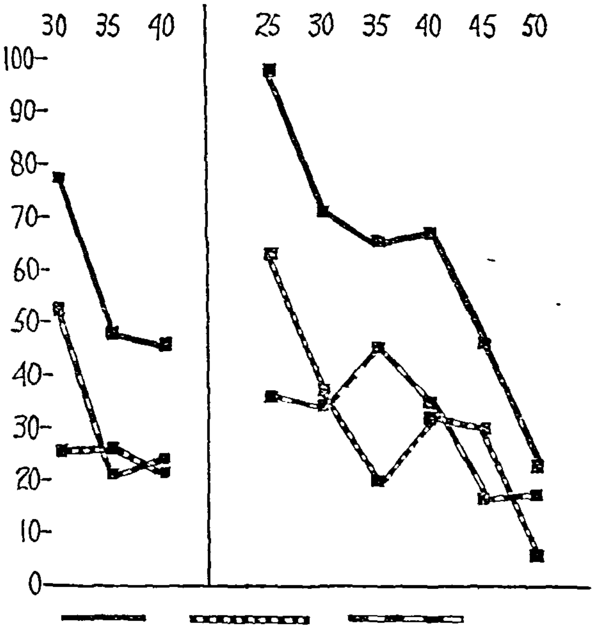
TEXTURE OF SOIL AND HOOKWORM INFECTION.

Stiles (1903) reported as finding in 1902 that in the United States hookworm disease affected dwellers over sand far more than those over clay, an observation since amply confirmed. Accordingly it seemed well to ascertain whether the size of soil particles influenced larval development in the cultures described. To do so the dried and powdered garden soil which for all other cultures had been passed through metal gauze with 25 meshes to the linear inch, was again sieved through metal gauze having 100 meshes to the linear inch. In this way there were obtained from the same material two soils differing only in texture (here referred to as fine and coarse), one containing all matter which passed through a sieve with 100 meshes to the inch, and the other all which passed through a sieve with 25 meshes but failed to pass that with 100. To draw fair conclusions from these two sets of cultures has had difficulties. In a batch of cultures containing the same earth, fæces, and water, it happens now and again that a clutch fails completely while others are successful; some unknown factor has intruded. In one instance two clutches, all containing coarse earth, completely failed, while two with fine earth produced plentiful larvæ. But it was clear from other clutches containing both fine and coarse cultures that so far as soil texture went this failure was fortuitous. Accordingly comparison has been restricted to cultures which have not only used the same fæces but which (when the same clutches have contained cultures with both textures of soil) have given results sufficiently parallel, in those using the same soil texture, for the conclusion to be drawn that some unknown factor has not been at work in them. Fourteen cultures of each type fall into this category, each pair being also comparable in all other known respects. From the 14 fine cultures 2382 larvæ in all were recovered, and from the coarse ones 2265. Fineness of soil particles with which fæces may be mixed (whether artificially or naturally, as by insects) does not then seem to be the essential factor which lessens hookworm infection in clay districts; while if not so mixed the texture of the underlying soil and of the still more distant subsoil can hardly affect development in an overlying fæcal mass. The explanation, it is suggested, is as follows. The general acceptance of a negative geotaxis, an instinct for upward climbing, in hookworms is based on an inadequate foundation, and where evidence has been sought it is against that conclusion. Thus, Sawyer, Sweet, and Shaw (1923) found larvæ 6 to 12 inches below a fouled spot in sand overlying a compact mixture of sand and clay; and in three of six examinations Korke too (1926) found larvæ 12 inches below a place of pollution. These are the only references discovered of attempts to determine on these lines whether downward progression occurs. Infective hookworm larvæ, it is here suggested, emigrate in all directions from a polluted spot just as do infective strongyloides larvæ (Fülleborn, 1924). In a sand or gravel district where resistance to progress is relatively easy, and thigmotropism therefore relatively unimportant, erratic wandering will finally bring many to the surface even if at first they pass downwards. In a clay district those that reach the subsoil will penetrate its fine interstices along which no through passage exists. Here their overwhelming thigmotactic instinct will keep most of them busy trying to penetrate it till they die safe away from the surface. The relative freedom of clay districts from hookworm infection will, then, be due to thigmotaxis associated with the absence of a negative geotaxis.

THE EFFECT OF WATER CONTENT.

Soil from a garden overlying the London clay when left to dry contained from 2·5 to 4·5 per cent. of water as measured by the loss of weight which occurred when heated for half an hour over a water-bath. Dust-dry soil which had passed through wire gauze with 100 meshes to the linear inch contained 3 per cent., while that fraction of the same soil which had passed through 25-mesh gauze contained 1·75 per cent. As has been reported (Lane, 1930), fæces have been shown to contain from 68 to 97 per cent. of water, and neither figure should be taken as defining limits, nor is the water content proportional to the physical consistency. The percentage of water in the selected mixture of four parts of earth and one of fæces has averaged 20·3 (19·2 to 21·25).

FIG. 1. FIG. 2.



Some effects of the water content of cultures on the development and migration of hookworm larvæ.—The vertical figures show the percentage of eggs, set for culture, accounted for as infective larvæ. The horizontal figures show the mean percentage of water which the cultures contained; in Fig. 1 this did not vary more than two and a half, in Fig. 2 more than 5 per cent. in either direction from that mean throughout the period between setting and extracting the cultures.

The manipulations described under cultural methods have been applied to 547 cultures and have entailed 2938 weighments to within 0·01 g., and a large number of measurements of water to within 0·01 c.cm., and the calculation of the percentage of water which nearly every measurement has implied. Many cultures have been of use rather to show points in which technique required alteration or directions likely to prove valuable for investigation than in leading directly to conclusions. But after means were discovered to keep the water content of cultures fairly steady, certain definite results emerged. Fig. 1 deals with 37 cultures in which the water content from beginning to end varied in each direction within 2½ per cent. of the mean indicated; Fig. 2 deals with 17 cultures in which it varied within 5 per cent. of the mean shown; and since these, too, are arranged to show variations of 5 per cent. of water, it is clear that except at the extremes of the scale each culture appears twice. The graphs show that within the limits of 25 and 50 per cent. of water, the less water there was, the more readily was development carried to the infective stage; while the relative percentages of larvæ migrating from cultures and of those remaining therein were too erratic to suggest that any lessons could confidently be drawn from the differences. It is noteworthy that in these cultures the number of larvæ which failed to migrate—which remained at what would have been in nature the infected spot—was 32 per cent.

Regarding consistence of the cultures, at the lower end of the scale they broke into rather large granules, but might be clayey at the angle between the side and bottom of the Petri dish; at the upper end the consistence was a moist clay, but the cultures were not submerged. With this particular mixture of earth and fæces, development occurred to the extent of 14 per cent. with a water content as high as 60 per cent., and so far as the few experiments went they indicated that the factor which limited development was submergence of the culture medium rather than its water content. At the other end the accompanying Table shows the amount of development which occurred when the percentage of water became low, the cultures having been set up before the means were devised of keeping it fairly constant. Notes made before extraction described these cultures as powdery, flaky, or granular. The Table brings out two points. The water content fell below 9 per cent. and the cultures became a coarse powder from which little success in extraction was expected, and yet in one case 57 per cent. of the eggs reached infectivity while the average was 30 per cent. The second point is that with the percentage of water so low as this little migration took place.

Table Showing Development of Infective Hookworm Larvæ in 4 to 1 Earth-Fæces Mixtures with a Low Water Content.

Percentage of water in culture on—			No. of eggs by D.C.F.F.	Percentage of eggs becoming infective larvæ by day 8 as shown by—		
Day 1.	Day 3, 4, or 6*	Day 8.		Trapping.	Extraction.	Total.
20·2	14·2 (3)	15·1	505	11·4†	77·0	88·4
20·2	16·0 (3)	15·1	505	11·4†	64·5	75·9
20·2	16·0 (3)	16·9	505	11·4†	55·3	66·7
21·2	17·9 (4)	18·75	391	0·25	21·2	21·45
21·2	15·3 (4)	19·6	391	0·0	50·7	50·7
21·2	15·3 (4)	16·2	391	0·0	4·9	4·9
21·25	9·0 (6)	10·9	209	0·0	8·1	8·1
28·4	8·8 (6)	10·7	209	0·0	57·0	57·0
28·4	11·8 (6)	28·4	209	0·0	49·8	49·8
21·0	13·2 (4)	14·1	209	0·0	25·8	25·8
19·6	8·6 (3)	18·1	79	5·1	8·9	14·0
19·6	9·9 (3)	14·7	79	2·5	19·0	21·5
19·6	8·4 (3)	14·6	79	3·8	29·1	32·9

* The day of intermediate weighment in brackets; on it, loss of weight was exactly made up by added water.

† An average; 230 larvæ escaped into a trap common to these three and a fourth culture.

Hygienic Implications.

Hygienic implications are these. It has been confidently assumed, and the assumption has led to most confident advice on the conduct of hookworm campaigns, that at certain seasons of the year in certain endemic localities, the condition of the soil is such that the possibility of reinfection must in practice be disregarded. These experiments indicate that in such dry surroundings infective larvæ are produced from about a third of the original number of eggs, and that almost all of these larvæ then remain at the infected spot. It is perhaps significant that, as noted above, it is almost exactly this percentage which failed to migrate in more favourable water conditions. Now the writer has for over 12 years (Lane, 1919) stressed his conviction that the acquisition of hookworm infection is essentially dejectional, acquired during defæcation at a "natural" or a man-made privy. It will hardly be disputed that in a dry locality such a latrine is likely to be one of its less dry spots, particularly among races where water is used to cleanse after defæcation. These experiments show that dryness has a strong action in limiting infection to the infected spot, and suggest that the liability to dejectional infection—the predominant type of infection—need not be materially lessened during dry seasons in endemic areas. There is certainly no justification for the common assumption to the contrary, and such mere guesses should no longer have pride of place in hookworm campaigns. In support of this conclusion two cultures not cited in the Table are noteworthy. From them 1420 and 831 larvæ escaped in the first 32 days, during which the water content had remained very close to 40 per cent. The number of eggs in each had been 2375. During the next fortnight they were neglected and became dry and friable, and only 26 and 1 larvæ were trapped. Yet on extraction of these dry, friable cultures, whose water contents were 12·4 and 9 per cent. respectively, there were recovered 279 and 214 larvæ which showed marked activity. A dry friable soil such as has been deemed harmless was in fact so dangerous that the amount of it which might have adhered to the sole of a foot after the wetting resulting from post-dejectional ablution, would have contained many hundreds of vigorous infective larvæ a month and a half after the original stool had been passed. Hookworm campaigns should not, on a priori grounds, be timed for certains seasons of the year. Whether or not the privies, or spots favoured for defæcation, can produce infective larvæ at all seasons of the year is a matter whose determination should at least be attempted locally. There should be no lighthearted assumption to the contrary.

These figures of the relation of water content to larval development apply only to mixtures of four parts of soil to one of fæces. It is not suggested that they define limits, nor are they likely to apply to mixtures in other proportions. Possibly they will not apply to all kinds of soil. In pure fæces development of infective larvæ has occurred with a water content maintained between 80 and 85 for four weeks. There is little exact knowledge on this matter.

Conclusions.

Investigation of 547 earth cultures has shown emphatically that emigration of infective hookworm larvæ from them is frequent and may be very great, and accordingly that the many conclusions regarding larval biology, including longevity, conclusions which are mainly based on untrapped cultures, rest on so precarious a basis that they certainly are far from exact; that properly constituted larval traps have a high efficiency, and that any failure presumably lies in the make-up of the individual trap; that there is a method of extracting larvæ, economical of space and allowing of this being done under exact conditions of temperature, which is not less efficient than that in general use; that to submit material to larval extraction for a few hours does not accurately measure its possible, perhaps not its momentary, infectivity; that the effects of texture of subsoil on the local prevalence of hookworm infection is reasonably explicable if hookworm larvæ migrate through soil and subsoil in all directions, and are without that negative geotaxis which is commonly postulated—it is believed incorrectly, and certainly not merely without adequate evidence, but against some that exists; that if it is as safe as it seems to generalise on over 50 cultures of a mixture of four parts of earth and one of fæces, conducted with close checking of the water content, larvæ develop best when this is as low as 25 per cent.; that even when in these conditions it falls as low as 9 per cent., and the culture is powdery, more than half the eggs may have developed into infective larvæ, and that these may be so vigorous as to constitute of such infected soil a spot of intense infectivity; that these dry conditions need not lessen the infectivity of an infected spot, though they may annul migration of larvæ from it; and that since infection in backward races is mainly dejectional, obtained during defæcation, drought need in no way lessen the infectivity of those spots which are favoured by and returned to by such people day after day for this purpose, especially if they wash the parts on the spot. There is then no present justification for assuming that in certain regions and at certain seasons the possibility of acquiring infection must be disregarded. It is wiser to find out and not to guess.

OPHTHALMIC HOSPITALS.—Last year the Birmingham and Midland Eye Hospital received 1968 in-patients whose average length of stay was somewhat increased. The average weekly cost of each in-patient fell by 2*s.* 10*d.*, but in consequence of the longer stay the cost of treating each in-patient to a conclusion was 5*s.* 4*d.* more. There were 41,330 new out-patients, 22,021 of whom were casualty patients; 13,841 of them were attended for the removal of foreign bodies in the eye. The reduction of over 4500 in this type of case is considered to be indicative of the depressed state of industry. Excluding the casualties, the average cost of each out-patient was 5*s.* 4*d.* Spectacles were prescribed in 9436 cases. Mr. Jameson Evans, chairman of the medical board, states that the pioneer work of slit-lamp investigation and orthoptic treatment of squint, which has been carried on for some years, is showing "very valuable results" which it is hoped to publish in due course. He trusts that it may presently be possible to establish a research endowment fund.—Last year the Victoria Eye Hospital, Hereford, received 261 in-patients and treated over 3000 out-patients.

MEDICINE AND THE LAW.

Marriage Annulled for Lunacy.

ON March 21st Lord Merrivale granted a decree nisi of nullity on the ground that the respondent, at the time of the ceremony of his marriage, was insane and should not be bound by that ceremony. There were some indications, said Lord Merrivale, that the respondent had a vague idea about marriage; but he was not in a condition to carry out any responsible duty. He was in the hands of those who were about him; they thought the marriage was a good thing for him and carried on with it. He did mechanically the things which are done at a ceremony of marriage, but he was at that time insane. The test is whether a person has the mental capacity required to enter upon any responsibility—whether he has such mental capacity as enables him to bind himself to any obligation. If there is unsoundness of mind, is it such as to disable him from understanding the nature of the contract?

Though many reformers would desire to see the law so changed, lunacy occurring after marriage is no ground of divorce. In a leading case of 1885 the Earl of Durham sought to have his marriage annulled on the ground that his wife had been insane at the time of the marriage. He could show that she had since become insane, but the Court, after a patient examination of the evidence of several eminent doctors, came to the conclusion that the insanity had developed after marriage; his petition was therefore dismissed.

To marry a "lunatic so found by inquisition" was originally a contempt of court, punishable by imprisonment like any other form of contempt. In 1742 Parliament passed an Act to prevent the marriage of lunatics. "Whereas persons who have the misfortune to become lunatics"—so ran the preamble—"may by reason of such their disorder be liable to be surprised into unsuitable marriages which may be of pernicious consequence and a great misfortune to their families"; it was therefore enacted that a lunatic should not marry till declared of sane mind by the Lord Chancellor. This is still the law, by virtue of an Act of 1811. Some will wonder how these marriages are ever allowed to occur. Lord Merrivale directed in the recent case that the papers should be sent to the King's Proctor "for inquiries to be made, to secure that there was no departure from the ordinary course of justice." Instances of this kind may reinforce the demands of the eugenical reformers for some kind of check on the marriage of the unfit. A man cannot drive a motor-car without making a declaration of fitness: marriage may be undertaken without even this formality.

Workmen's Compensation—Delay in Claim.

Under Section 14 of the Workmen's Compensation Act the claim for compensation must be made within six months of the accident. It has been held that this condition is of substantial importance, and not a mere technicality. But the Act adds a proviso that failure to claim within the time limit is not to bar proceedings if the failure was occasioned by "mistake, absence from the United Kingdom, or other reasonable cause." Whether the facts amount to reasonable cause has been held to be a question of law which is open to review on appeal. If a workman honestly believes his accident is not serious, and if it turns out that this belief is mistaken, the Courts have accepted these circumstances as reasonable cause for the failure to claim.

On Feb. 20th, 1931, a Lancashire workman was hit in the eye by a chip of stone. He told a director of the employing company of his accident; he himself thought it was a trivial matter; so did the director. The workman had had bits of stone in his eye before without serious injury. His eye troubled him; he bathed it and wore a shade; but he managed to work to his employers' satisfaction. In April he went to his doctor, who said it was a case for specialist ophthalmic treatment, and gave him a note to take to an eye hospital; but the workman did not go. On May 23rd he was discharged owing to slack trade. In June he told a friend he had lost the sight of his left eye. He did not in fact lose it till August. After losing the sight of his eye, he made his claim for compensation. The County Court judge found that the failure to make the claim within six months was due to a reasonable cause. Although the workman's story in the witness box contained flagrant inconsistencies, it was entirely honest. The Court of Appeal has upheld the decision.

Posing as a Doctor.

Recent proceedings at Long Ashton police-court, near Bristol, reveal another instance of an unqualified man adopting the name of a medical practitioner and successfully posing as a qualified doctor.

Described as William Faulkner, alias Norman Nelson Kirkup, the accused was charged with posing as a Bachelor of Medicine between March and October, 1931, and with falsely using the title of Dr. Kirkup or Dr. Norman Nelson Kirkup, M.D., implying that he was recognised by law as a practitioner in medicine. The accused, who was extradited from Singapore on other charges, was stated by the prosecution to have adopted the name Norman Nelson Kirkup which was that of a medical practitioner at one time in Detroit. It was said that he applied for the post of assistant medical officer at the Bristol Mental Hospital, enclosing two references from Canada, where he said he was an M.C.P.S. He obtained the post, and for six months carried out his duties more or less successfully. Faulkner pleaded guilty to these two charges and was fined £20 on each. He was committed for trial on other charges of quite a different nature—bigamy and obtaining money by false pretences. In opening the case on the bigamy charge, the prosecution stated that Faulkner last year obtained a post as assistant medical officer in North Borneo with the British North Borneo Chartered Company; it was while going to take up that appointment that he was arrested. There was another charge against him for obtaining money from the company by representing himself to be a doctor and thus receiving money for outfit and salary. To these charges he pleaded not guilty; he has reserved his defence and stands committed for trial.

The fine of £20 imposed in respect of the charges to which Faulkner pleaded guilty is the maximum penalty under Section 40 of the Medical Act. In discussing a similar case recently, it was pointed out that the equivalent maximum penalty under the Dentists Act is £100. Some members of the public may not mind whether they are treated by the qualified or the unqualified; but, if a patient or an institution prefers a qualified practitioner, there must be no confusion as to which is which. The annoyance inflicted on a registered medical practitioner if his name and qualifications are coolly annexed by an impostor is a grievance to which Parliament might well pay attention. Two such cases have already been before the courts lately.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Comdr. G. A. S. Hamilton is placed on the retd. list.

Surg. Lt. C. N. H. Joynt is transferred to the permanent list.

ROYAL ARMY MEDICAL CORPS.

Maj. (temp. Lt.-Col.) A. Hendry to be Lt.-Col.

The undermentioned Lts. on prob. are restd. to the estabt.: L. T. Furnivall and J. K. Chappell.

The undermentioned to be Lts. (on prob.): H. J. R. Thorne (and is confirmed in his appt.), E. W. Gibbs, P. T. L. Day, and J. V. Quinn.

ARMY DENTAL CORPS.

Lt. G. E. Nettleship to be Capt.

ARMY RESERVE OF OFFICERS.

Lt.-Col. D. L. Harding, having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

Lt. J. T. McOuat to be Capt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Col. A. M. McIntosh (late R.A.M.C.), having attained the age limit, retires, and retains his rank, with permission to wear the prescribed uniform.

INDIAN MEDICAL SERVICE.

Majs. to be Lt.-Cols.: J. W. Jones, L. A. P. Anderson, W. C. Paton, J. B. Hance, H. K. Rowntree, B. F. Eminson, A. Kennedy, C. McIver, and J. C. John.

Lt.-Col. A. H. Napier retires.

HONORARY SURGEON TO THE KING.

Lt.-Col. & Bt. Col. P. H. Mitchiner, T.D., R.A.M.C. (T.A.), has been apptd. Hon. Surg. to the King, vice Col. R. E. Bickerton, D.S.O., T.D. (ret.).

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED MARCH 19TH, 1932.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 61 (last week 76); scarlet fever, 1582; diphtheria, 811; enteric fever, 28; pneumonia (primary or influenzal), 1718; puerperal fever, 33; puerperal pyrexia, 113; cerebro-spinal fever, 56; acute polio-myelitis, 4; acute polio-encephalitis, 1; encephalitis lethargica, 11; dysentery, 17; and ophthalmia neonatorum, 97. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on March 22nd–23rd was as follows: Small-pox, 105 under treatment, 3 under observation (last week 110 and 6 respectively); scarlet fever, 1444; diphtheria, 1517; enteric fever, 9; measles, 2331; whooping-cough, 416; puerperal fever, 23 (plus 7 babies); encephalitis lethargic [illegible] 4; "other diseases," 182. At St. [illegible] ere were 10 babies (plus 6 mothers [illegible] natorum.

Deaths.—In 117 great towns, including London, there were no deaths from small-pox, 3 (1) from enteric fever, 116 (47) from measles, 5 (3) from scarlet fever, 56 (12) from whooping-cough, 21 (5) from diphtheria, 66 (22) from diarrhœa and enteritis under two years, and 230 (40) from influenza. The figures in parentheses are those for London itself.

The diminution in mortality from influenza continues: outside London the largest number of deaths (16) was reported from Bristol; there were 9 in Stoke-on-Trent, 8 each in Birmingham and Leicester, and 6 each in Sheffield and Croydon. Nine of the fatal cases of measles were assigned to West Ham, 8 to Manchester, 5 to Liverpool, and 4 each to Portsmouth and Leeds. Seven deaths from whooping-cough were recorded in Birmingham and 5 in Liverpool. Six of the deaths from diphtheria were in Hull.

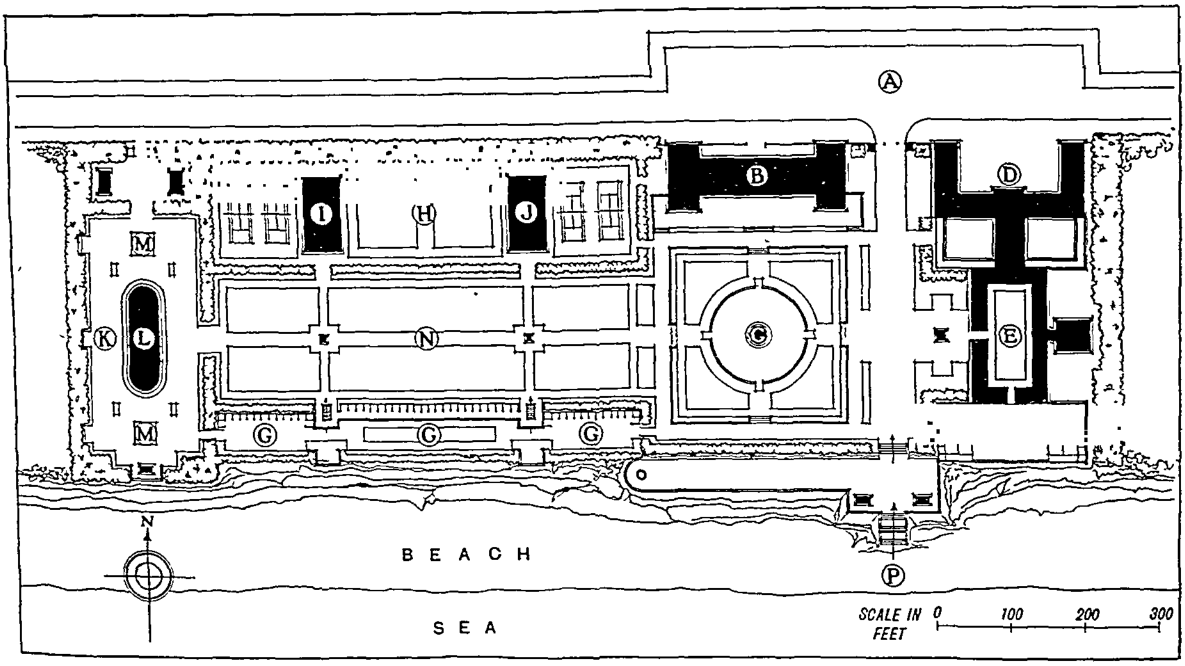
The number of stillbirths notified during the week was 291 (corresponding to a rate of 41 per 1000 total births), including 47 in London.

AN ALL-WEATHER HEALTH AND SOCIAL CENTRE FOR A SOUTH COAST RESORT.

By Marshall Sisson, A.R.I.B.A.

THE curative virtues of the British coast resorts are becoming more widely recognised, but in the opinion of many medical men the accommodation offered to invalids and holiday-makers for their treatment and recreation is not always sufficiently adapted to the climate. It is essential that visitors to the coast shall be able to enjoy the advantages of sea air, bathing, exercise and amusement under pleasant conditions at all seasons and in all weathers.

Some health resorts already possess admirable specific features, and others are now considering improvements; but, owing to a lack of forethought in planning in the past, the individual resources are often uncoördinated, with a consequent loss in amenity and convenience. Careful grouping of the scattered elements on a site reserved and previously planned to receive them would go far to supply any deficiences and to augment the advantages of a resort by forming a convenient health and social centre. There would be in a garden setting a restaurant pavilion and bandstand, a medical bathing establishment, a swimming-bath and sheltered area for sunbathing, covered shelters and quiet retreats for invalids, indoor tennis-courts and bowling-greens, and a separate playground for children. Such a centre should be readily accessible, close to the seashore, open to the sun, and screened from cold winds.



Plan of the Centre. A, main entrance; B, restaurant pavilion; C, bandstand; D, medical baths; E, swimming-bath; F, sunbathing area; G, sunk gardens and shelters for invalids; H, tennis-courts and bowling-greens; I, covered tennis-court; J, covered bowling-green; K, children's playground; L, covered playground; M, paddling pools; N, ornamental garden; P, way down to beach.

The accompanying diagrammatic plan has been devised to show how these various elements might be combined in one comprehensive scheme. For the purpose of demonstration, a site of about ten acres, close to the seashore, has been assumed. In any actual circumstances the lay-out would necessarily be influenced by the nature of the site and the particular requirements of the locality.

The buildings provided have been arranged in a garden setting, accessible from the town and from the beach, and terraced and planted so as to give views of the sea and shelter from the north. The gardens might be screened with plantations and thick masses of shrubs as these would probably grow better near the sea than larger trees. The restaurant pavilion (B), next to the main entrance to the gardens, commands a view of the sea. This block might contain, in addition to a restaurant, dancing, reading, and card rooms, and possibly a concert room. In fine weather the terrace outside would be used as a café. In front of the restaurant is a bandstand (C), set in the centre of a sunk area surrounded by covered shelters designed to accommodate a large audience in showery weather. At the east end of the site, and approached directly from the road as well as from the gardens, is the medical bath unit (D). This might contain: Turkish baths; vapour and switching room; douches and hot-air appliances; whirlpool baths; sedative pool; dry inhalation room; radiation and manipulation room; slipper baths for effervescent, foam, aerated, hot salt, and seaweed treatment; gymnasium; and consulting and waiting-rooms. Adjacent to the medical bath building is a covered swimming-bath (E) and on the south side of this, next to the sea, a sheltered space for sun and air bathing (F). The swimming bath might be made more attractive by the provision of a modification of the artificial wave mechanism which has proved very popular in various continental baths but has not yet been installed in this country.

Covered shelters to accommodate a large number of invalids and others are provided in a secluded position next the shore. These shelters, facing south, are arranged in sunk gardens (G) so as to be screened from all winds, those from the sea being excluded by banks and hedges. A pool to reflect rays and sloping approaches for wheeled chairs are suggested. The northern part of the garden contains tennis-courts and bowling-greens, both open and covered (H, I, J). At the west end of the site is a playground for children (K), with a separate entrance from the road. This section contains a large playing shed (L) and paddling pools (M). Separate cloakrooms and hot foot-baths for use after paddling would be provided near the entrance. In addition to these more important elements, attractive kiosks for the sale of papers, flowers, milk, tobacco, and confectionery, might be incorporated at suitable places in the grounds.

The buildings included in such a scheme should be simple in character and light and economical in construction. Much of the architectural effect would depend on their relation to one another and to the garden setting. A judicious use might be made of colour-wash, which could easily be renewed so as to keep the buildings fresh and gay.

Unfortunately, most seaside resorts do not provide a clean slate for the planning of a comprehensive scheme of this kind, but in many cases where some of the constituent parts already exist, complementary ones might be added in close relation to these so as to remedy deficiencies and produce a complete and coherent whole.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

INSURANCE PRACTICE.

NEW regulations on club-practice have lately been issued by the government, with the agreement of the association of sick-clubs (Krankenkassen) and of the Hartmannbund on behalf of the medical profession. The principal points are that a medical man wishing to engage in club-practice must enter his name in a register to be kept by the district insurance office. Only German medical men who have been qualified at least two years are entitled to registration, and there is to be one doctor for every 600 club members. No medical man who receives a fixed salary of 500 M. a month or more from the government or from a private company or association may have his name on the club register. Married medical women enjoy the same privileges as the unmarried, and practitioners may not be denied registration because they are married, nor because they describe themselves as homœopaths. Those who took part in the war, and especially those who were disabled or who suffered exile from the territories formerly belonging to Germany, enjoy preference over other candidates, and so do those who have already lived for a long time in the locality. Special items concern the registration of specialists, and the replacement of medical men who have died or have given up practice. The new regulations have certain advantages over the old ones, for the number of medical men admitted to club-practice (which has hitherto been one for every 800 members) has been increased and the time for admission after qualification has been shortened so that several hundred more young practitioners may be admitted.

MEDICAL ASPECTS OF LONG CYCLING RACES.

Dr. Conrad, writing in the *Deutsche Medizinische Wochenschrift*, has described his experiences of the six days' cycling races, at which he has acted for many years as medical adviser. He points out that the professional six days' cyclist must be attended on different lines from the ordinary patient. Treatment of causes is of course impossible, quick help being wanted to enable the cyclist to continue the race. One of the most common ailments is laryngitis, due to the dust produced by the cyclists, the tobacco-smoke arising from onlookers, bad air, and irregular ventilation. As a quick-acting remedy he recommends a compound of tinctura aconiti, menthol, bromoform, and codeine. The pressure of the saddle sometimes produces maceration of the skin of the buttocks which by the action of sweat may lead to necrosis or to severe folliculitis. He has found brushing the skin with salicylic spirit useful as a prophylactic measure. A dislocation of the shoulder, if properly reduced, need not prevent the competitor from continuing his race, though this is against the general rules of surgery. The reduction must be performed under brief narcosis, the shock always connected with accidents not allowing deep anæsthesia, while postponement of the reduction until shock has disappeared is impossible. To strengthen the heart, strained by the exertion of the race, injection of cardiazol is advisable before the reduction. Gastric and intestinal troubles are common in professional cyclists, but they are very sensible about their food. Formerly they even brought their own cook with them, but now a German cook prepares the meals according to their accustomed diet. Owing to the sensitiveness of their intestines stimulating preparations must be administered as little as possible by mouth and preferably only by inhalation or injection.

REPRODUCTION OF CARDIAC SOUNDS.

At a recent meeting of the Berlin Medical Society Dr. L. Jacobsohn showed a method of reproducing cardiac sounds and murmurs on the principle by which sound films are made. He has calculated the rate of vibration of these sounds and has thus been able to compose them as sound pictures. By checking the sound pictures classified in groups of vibrations the method has been developed to such an extent that in the loud speaker the difference between the natural and the artificial sounds is no longer distinguishable. The sounds were clearly audible when demonstrated to the society, and they aroused a lively interest among the audience. Prof. Goldscheider, the president, said that Dr. Jacobsohn's device would be of great use in medical training.

DIAPHRAGMATIC HERNIA.

Prof. Gustav von Bergmann, head of the Medical Clinic of Berlin University, in a paper on Hernia of the Œsophageal Hiatus in the Diaphragm, read before the Berlin Society for Internal Medicine, says that that condition is not so rare as is believed, for about 300 cases have been seen in his clinic in recent years. Radiography, by which the diagnosis is made, gives results only when the patient is in the Trendelenburg position. Though not a hernia from an anatomical point of view, since no hernial sac exists, the condition is not a physiological variation but is definitely pathological, nearly all the patients complaining of pain at the ensiform process and of a feeling of oppression. Gastritis and even severe gastric hæmorrhage may result from the disturbance of circulation caused by the compression of the protruded portion of the stomach. In radiograms shown before the society a part of the stomach was visible above the diaphragm. Treatment consists in reduction of the hernia by inflation of the stomach and by gymnastic exercises; riding has given good results.

CORRESPONDENCE

REFERRED PAIN IN VISCERAL DISEASE.

To the Editor of THE LANCET.

SIR,—Your annotation on Prof. D. W. Carmalt-Jones article on Tender Rib Cartilage as a sign of Cholecystitis in THE LANCET of March 19th again raises the question of the nervous mechanism of referred pain in visceral disease. I am inclined to believe that the explanation of the phenomenon described by Prof. Carmalt-Jones is that a hyperalgesic area of skin and subcutaneous tissue was pressed against the rib cartilage, not that the rib cartilage itself was tender; a point which might be settled by subcutaneous infiltration with novocain.

The major question, however, remains. Does a viscero-sensory reflex as described by Mackenzie exist? Or is Mr. Morley's later theory to hold the field? I have just read Mr. Morley's recently published interesting monograph on abdominal pain, in which he postulates a peritoneo-cutaneous radiation theory as an explanation of certain clinical phenomena. He asserts that a viscero-sensory reflex does not exist, and seeks to explain the occurrence of hyperalgesia, superficial and deep tenderness as being phenomena referred from the highly sensitive cerebrospinal nerves of the parietal peritoneum. Yet on page 151 Mr. Morley says:

> "When we explore an abdomen under a general anæsthetic such as ether, we find a complete absence of intestinal movement. The small intestine which we know from X-ray observations to be under normal conditions, in constant peristaltic movement, lies completely immobile in the opened abdomen. This immobility appears to be due to *a reflex effect from stimulation of the parietal peritoneum by our incision, giving rise to an efferent impulse down the splanchnic nerves and an inhibition of intestinal movement.*" (The italics are mine.)

Surely Mr. Morley here postulates a true viscero-sensory reflex?

Again, how often have we all picked up the skin and subcutaneous tissue of the abdominal wall and elicited visible peristalsis in cases of obstruction. How other can this phenomenon be explained than by the existence of a viscero-sensory reflex?

I am, Sir, yours faithfully,

St. Leonards-on-Sea, March 23rd, 1932. DAVID LIGAT.

THE DURATION OF THE RED LOCHIA.

To the Editor of THE LANCET.

SIR,—The interest of Mr. Chassar Moir's able article in THE LANCET of March 12th centres in the fact that a large number of women after confinement suffer from intermittent or persistent bleeding from the uterus for varying periods beyond the text-book standard. If these cases are not treated it is my belief that many of them will later find their way to the gynæcological wards to undergo curettage or even hysterectomy. In a lecture to the Blackburn Division of the British Medical Association in 1928 I quoted some statistics from welfare centres. One centre recorded that during the year 50 women who had been confined were found to be still bleeding for weeks or even for months afterwards, and 20 of these cases actually came from St. Mary Abbots Hospital. As a result of a long series of observations, I have no doubt in my own mind that the hæmorrhage was secondary to an inflammatory condition of the uterus.

Prof. Robert Donaldson has also informed me that 70 per cent. to 80 per cent. of curettings received from the gynæcological department were inflammatory in type and that probably in many cases the inflammation dated from a previous labour or abortion. I would modestly suggest that where there is a prolongation of the red lochia the hæmorrhage is secondary to an acute or chronic inflammatory condition of the tissues of the uterus. In the case of the last 910 deliveries at this hospital, the prolongation of the red lochia after the seventh or eighth day, occurring in 72 of these, has been regarded as a sign of morbidity. Evidence of antenatal sepsis, malposition or abnormal labour was found in 55 per cent. of these cases. The question therefore arises, Can these cases be controlled by treatment? The answer is Yes, by glycerin irrigation, which, by promoting free drainage, relieves the inflammation which is responsible for the hæmorrhage. Again, these women in whom the lochia are prolonged, provide about 50 per cent. of our cases of puerperal sepsis. As a result of a careful investigation of 340 consecutive deliveries I have found that 80 of them showed signs of sepsis, 40 of them having pyrexia and 40 having prolonged red lochia after the first week without pyrexia. It is illogical, in my opinion, in estimating the part played by sepsis, to select as instances of sepsis only those who showed a rise of temperature. We must realise that there are degrees of sepsis and of inflammation and this is a fact which is not sufficiently appreciated. In many cases of peritonitis in women following childbirth or miscarriage, it is difficult to trace the origin of the infection, but if careful inquiry is made into their history it will be found that these patients have had prolonged lochia for some weeks. This, to my mind, is an indication that the uterus was left in a condition of chronic inflammation. Finally, although it is difficult to draw a dividing line clinically between what is physiology and what is pathology after delivery or abortion, I would suggest that where the red lochia persist beyond the seventh or eighth day glycerin treatment is to be commenced; otherwise, the high rate of morbidity now existing will continue.

I am, Sir, yours faithfully,

A. REMINGTON HOBBS.

St. Mary Abbots Hospital, Kensington, W.,
March 22nd, 1932.

THE INSURANCE OF PEDESTRIANS.

To the Editor of THE LANCET.

SIR,—You are to be thanked by drivers and walkers alike for the temperate tone of the article in your issue of March 19th on the proposal that motorists shall be liable to pay damages whether or not a road accident was caused by the driver's negligence, and whether or not the walker contributed by his negligence. This well-meant but most undesirable proposal enshrines the walker's suicidal notion that he has rights but no duties on the carriage way. This notion is the indirect cause of countless mishaps. The French provision of a small fine of one franc (2½*d.*) for a jay-walker has the opposite psychological effect and saves life by inducing responsibility. No doubt the absence of any footway to long stretches of country roads in England is a reproach, but as the voting power of motorists is only about one-twentieth of that of walkers, the motorists are not chiefly to blame (especially as they pay £60,000,000 a year to the exchequer as motorists in addition to their contribution to the highway rates).

I am, Sir, yours faithfully,

MERVYN O'GORMAN.

Embankment-gardens, S.W., March 29th, 1932.

PROPHYLACTIC PLASMOQUINE ON A TEA ESTATE.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Dec. 26th, 1931, there appeared a letter under this heading and with the signature of Sir Malcolm Watson, of the Ross Institute. I wish to reply to it as briefly as possible.

In 1925 I visited the Travancore Tea Companies' Estates and spent about four weeks investigating malarial conditions. In the malaria season of 1926 the company agreed to my being there for a period of six weeks to start up antilarval and other measures. In 1927 I spent four weeks on these estates helping with the work and supervising all arrangements, particularly the oiling, which was on the whole very well carried out. Dr. J. H. Moore was stationed in this area and gave valuable help, especially with the treatment. In 1927 I came to Ceylon and have not been able to visit the estates since.

In 1928 Sir Malcolm Watson paid a visit of five or six days only to the estates; leaving Travancore he came to Ceylon and was very reticent about any recommendations that he had made in Travancore, but remarked that on one or two estates he recommended extending the area to be oiled. On June 11th, 1929, I wrote and asked him would he kindly let me have a copy of any report that he might be writing on the Vandiperiyar estates, as I was interested in them; on August 2nd, 1929, he replied as follows:—

> *Some time ago I got a letter from you asking if I would send you a copy of any recommendations I made about Vandiperiyar. I have not made any written report about Vandiperiyar, but some time ago Mr. Sylvester, the manager, came to the Institute and discussed the estates with me.*
>
> *As you know Mr. and Mrs. Cantlay have done such good work that there was little to say on the subject. I think my only recommendations were that a definite area of a quarter of a mile, round the lines, should be selected and controlled on each estate, and on one of the estates, Tungamullay I think I suggested, that some land should be acquired from the Government in order to complete the control work.*
>
> *It was, I think, Tungamullay where a swamp immediately below the lines and one or two other breeding places had not been controlled, and to these places I attribute the last outbreak of malaria.*

From the above it is obvious that at the time Sir Malcolm Watson himself did not consider that the slight increase in the area oiled was of very great importance. He now claims that this increase in the area oiled was the cause of the rapid decline in the malaria figures of 1929. Admitting that the area oiled was increased slightly, as was desirable, does he maintain that this would have reduced the percentage of parasites in the autumn blood slides from 73 per cent. to 7 per cent. and the gametocyte rate from 34 per cent. to nil in a year? There is conclusive evidence that our anti-gametocyte campaign, making use of plasmoquine, produced a very drastic reduction in the number of gametocyte carriers in the labour forces of the estates; therefore to say that this was not the main cause of the reduction in the number of reinfections and to attribute it to a very doubtful reduction in the number of anopheles is simply to acknowledge one's ignorance of mathematics. The area oiled was only increased in two estates, yet all showed improvement in the health figures. Further, it is possible to omit the figures on the two estates mentioned without upsetting my conclusions. Both Mr. Cantlay and Mr. Sylvester have informed me that there was practically no alteration in my original programme. Anyhow all the evidence and figures were published in two articles in the *Indian Medical Gazette* of December, 1930, and November, 1931. The figures speak for themselves, and I can confidently leave the final judgment to the readers of THE LANCET.

Plasmoquine assists the malariologist in the following ways: (1) in minute doses given to the gametocyte carriers it prevents the infection of mosquitoes (Barber, Newman, and Komp); (2) in medium doses (0·06 of a gramme spread over a week) it removes gametocytes from the blood (Knowles and Das Gupta); (3) in somewhat larger doses which have not yet been accurately determined for orientals, it prevents the infection after injection of sporozoits (James); (4) in two treatments (0·06 of a gramme over a week) it prevents relapses, reduces the number of carriers in a force and so reduces the number of infections (doses may not be adequate for all countries) (Clemesha and Moore).

The drug which has this remarkable action was given with very great care in accordance with my orders on all these estates, commencing September, 1928, and yet it is claimed that a slight increase in the area oiled (at the very outside of 10 or 15 per cent. on two estates out of nine) was responsible for the reduction in the amount of sickness on these estates.

I shall shortly be publishing some interesting graphs of badly infected estates in Ceylon, which have been kept practically free from malaria for more than two years by anti-gametocyte dosing with plasmoquine alone, antilarval measures being impossible on these estates. I do not propose to say much concerning the area to be oiled. In flat countries very likely the arrangements propounded by Sir Malcolm Watson answer satisfactorily in most years, but in mountainous countries, such as the Vandiperiyar Valley, they are useless. Anybody with an elementary knowledge of the habits of anopheles in hilly countries is well aware that these mosquitoes keep to the bottom of the valley and are also capable of travelling very long distances up and down ravines. Neither 20 nor 40 or much the larger number of chains are adequate to prevent invasion from outside in this type of country.

I do not propose to discuss the last two paragraphs of Sir Malcolm Watson's letter. One may search the book "Prevention of Malaria in the Federated Malay States" from cover to cover and not find the term "anti-gametocyte campaign" or very little that is in any way synonymous with it. Five years hence, when we know a little more about the uses and possibilities of plasmoquine, I think Sir Malcolm Watson's letter will cause a smile, and will be looked upon by the scientific world in much the same spirit as his pronouncement on plasmoquine at the meeting of the Industrial Anti-Malarial Advisory Committee of the Ross Institute, 1930, which the Editor of the *Indian Medical Gazette* discussed in his leading article of November, 1931.

There is one question which I would like to ask Sir Malcolm—namely, what was the cause of the complete breakdown of his oiling measures on the estates in the Federated Malay States in 1926. I have before me three reports of medical officers in that country; they all agree as to the facts—namely, that in spite of the most careful oiling, practically the whole of the labour force of estates was seriously infected throughout the whole Peninsula. I think I known the correct answer to this question, but I should like to know what so eminent an authority, as the writer of the above letter, thinks on the same subject.

I am, Sir, yours faithfully,

W. W. CLEMESHA,
Lt.-Col., I.M.S. (ret.), Malariologist to Control Scheme, Ceylon.

ÆTIOLOGY OF DISSEMINATED SCLEROSIS.

To the Editor of THE LANCET.

SIR,—Sir J. Purves-Stewart's and Dr. Hocking's communication in your issue of March 19th and your comments thereon justify other workers in giving their experience of vaccine therapy carried out on the lines originally instituted by Chevassut and Purves-Stewart. Since our first communiqué (THE LANCET, 1930, ii., 901) we have continued our treatment with an autogenous intravenous vaccine of 28 cases and re-examined the cerebro-spinal fluid after the course of injections. Although last year you informed us that, owing to the controversy as to the specificity of the so-called spherula insularis, you thought it wiser to abstain from publication of results until a larger volume of experience had been collected, we think it right that certain considerations should be laid before your readers so that they may draw their own inferences and conclusions, without bias.

From 1921–1929 disseminated sclerosis has been treated at Manor Hill Red Cross Hospital on the same lines as in other institutions—i.e., by intravenous arsenical injections. The rationale of this treatment was based on the alleged discovery by various observers of a spirochæte resembling but not identical with the *Spirochæta pallida* of syphilis. The spirochætal theory of causation having been discredited, the specific value of arsenic, such as neo-kharsivan, and silver salvarsan, would appear to vanish leaving only the tonic effect of arsenic and the empirical use of arsenic in any nerve disease to justify the continued use of arsenical treatment. In other words it is a case of "faute de mieux." So every doctor in charge of cases of disseminated sclerosis must have been hoping that a more specific treatment would be found. Chevassut's and Purves-Stewart's work appeared to hold out this hope, and it is certain that many like ourselves have been trying it out.

Unless results are published workers cannot compare notes and arrive at a conclusion. All we can do is to give honest impressions as to the value of treatment —i.e., from clinical and laboratory points of view. Pathologically the findings of cerebro-spinal fluid examination show definite changes after treatment. Clinically our experience has been that with a small range of doses—5,000,000 to 200,000,000—definite improvement has been shown. Second and third courses ranging from 20 to 600, and 50 to 1000 strength have had a uniformly bad effect. In this respect we regard one observation as being of definite value. During a second course two early cases received a dose of double the increase previously fixed on. Both had violent reactions—one was in bed for five days with weakness and increased spasm, the other with seriously impaired vision for three days. We have decided that for the present our dosage shall not be increased beyond 400,000,000. We think that it is a pity that Purves-Stewart and Hocking have not given their views on dosage. The only reference in the latest communication is to a course of 1–200,000,000. In the first communication, doses of over 1,000,000,000 were reported.

As regards the undecided question as to whether Chevassut's spherula is or is not the specific virus, we have an open mind. Different observers have differing opinions. We hold the view that, though it requires much practice to make the distinction, there are certain spherical bodies, distinguishable from commonly observed ones, which are almost always to be found in cases of disseminated sclerosis. We may add that we have never seen any filaments arising from the spherulæ. Whether these spheres constitute the actual virus or are merely an accompaniment of an unidentified virus, they at least afford a useful method of standardising the dosage of vaccine. In other words, we hold that the cerebro-spinal fluid of disseminated sclerosis contains a virus, vaccines from which have a definite effect clinically and pathologically on cases of disseminated sclerosis.

With regard to the empirical use of liver or massive doses of iron, it is probable that many are using one or other of these remedies in preference to vaccine—partly because they are equally experimental, and partly because of their easy administration—ignoring the fact that liver and iron treatment is based on the slender analogy of the subacute combined sclerosis complication of pernicious anæmia.

We are, Sir, yours faithfully,

A. C. RANSOME,
Medical Superintendent, Manor Hill Hospital, Birkenhead.

HUGH SMITH,
Hon. Pathologist to the Hospital.

March 28th, 1932.

To the Editor of THE LANCET.

SIR,—A letter from me in defence of Miss Chevassut was published in the issue of the *British Medical Journal* of March 14th, 1931, which was in answer to a criticism that appeared in the previous number. During the nine months which followed the publication of my letter I was in close touch with Miss Chevassut's work and methods. In the interests of the medical profession and sufferers from disseminated sclerosis I ask you to insert in your valuable journal this compressed account of the results of her work.

Early in 1931 the Halley Stewart Trust decided to provide a further opportunity for the trial of the method of treating disseminated sclerosis, based on the use of a vaccine prepared from cultures of a virus or organism, which Miss K. Chevassut claimed to have cultivated from the cerebro-spinal fluid of such cases, and described in an article in THE LANCET of March 15th, 1930. Premises were taken at 30, Chesterford-gardens, Hampstead, and equipped as a nursing home, with laboratories containing all the apparatus required by Miss Chevassut, to enable her to prepare the vaccine for the clinical trials, and to continue her investigations on the organism which she had described. Miss Chevassut, who was a grantee of the trust, was given the services of Mr. Lavington, who had acted as her laboratory assistant during her investigations at the Westminster Hospital. The institute provided a nursing staff and accommodation for 12 patients. I was appointed medical superintendent.

The institute was opened on March 29th, 1931, and by the end of the year 116 cases had been treated. Of this number 69 were readmitted on one or more occasions, thus providing opportunities for testing the results of the treatment. An analysis, drawn up by the medical assistant at the institute, of the results of these 69 cases is as follows :—

1. Cases showing considerable improvement ..	4 (5·80 %)
2. „ „ slight improvement	13 (18·85 %
3. „ „ no change of condition ..	25 (36·23 %)
4. „ definitely worse	27 (39·13 %
Total	69

These figures were submitted to Dr. F. M. R. Walshe, who has kindly given the trustees his views concerning them.

Dr. Walshe says, inter alia:

> "Your results amount roughly to this, that 25 per cent. of cases showed some measure of improvement (trivial in 20 per cent.) and 75 per cent. showed no improvement or definitely retrogressed. I may say with confidence these results are markedly worse than hospital records would show for the treatment on other lines of disseminated sclerosis, and also are not so good as a similar number of wholly untreated cases would probably show. I can only conclude from your figures that the treatment you have been investigating must aggravate the malady, and that the patients so treated are worse off than if they had been left alone."

Miss Chevassut made her first report to the trustees on her work in September, 1931. It was of a highly technical nature, and dealt with investigations in a number of different directions. It was submitted by the trustees to a committee of three eminent experts on pathology, and particularly on bacteria and viruses, who kindly examined the report and gave the trustees the benefit of their opinion. This opinion was entirely unfavourable, the committee expressing the view that the report had no scientific value. It described a successful cultivation of the specific organism, which she claimed could now be readily and regularly maintained in subcultures on solid media, and her records state that the organism was present in a very high proportion of the cases admitted to the institute during the six months from April to September, 1931. The committee therefore naturally desired to have the opportunity of examining the organism, and of verifying Miss Chevassut's detailed description of its microscopic and cultural characters. Miss Chevassut, however, was unable to furnish, for examination by the committee, a culture which she was willing to identify as that of the specific organism, but she readily promised to secure such a culture at the first opportunity. The trustees therefore, at a special meeting on Dec. 14th, decided to afford her a final chance of establishing her claim, and gave her the sole control of the laboratory, and the right to admit at least 12 cases for the period of a full month in which to provide positive cultures for verification by eminent scientists. She accepted these conditions but only admitted six patients, and having failed to produce from them a solitary culture she withdrew from the institute on Jan. 7th, a week before the expiration of the allotted month, and indicated her intention not to return. In view of the committee's adverse report, and her failure to produce a culture with the properties and appearances described in her report as characteristic of her disseminated sclerosis organism, which could be verified by independent investigators, the trustees had no alternative but to close the institute to her and abandon the trial of her method.

I am, Sir, yours faithfully,

B. H. STEWART, M.D.
(Trustee, Halley Stewart Trust.)

PS.—The above letter was drafted some weeks ago. The delay in submitting it for publication arose from a desire to have it approved by all concerned. Being written before your issue of March 19th it is in no sense a rejoinder to the article by Sir James Purves-Stewart and Dr. Hocking.

PERI-ARTICULAR ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—I should like to confirm the comments of your Paris correspondent on Dr. Leriche's method of peri-articular anæsthesia. Since reading the article in the *Presse Médicale,* I have applied the method to several cases of osteo-arthritis with considerable success.

The first patient was an old lady of 70 with osteo-arthritis of the right knee. Painful night starts were a trying feature. I found on examination that at two small spots near the internal lateral ligament it was possible by firm pressure to reproduce the spasm producing the night start. I infiltrated these spots with 0·5 c.cm. of percaine, and since that time there has been no recurrence of the night starts. Moreover, by further infiltration of two more painful spots, one at the inner border of the patella, and the other over the external lateral ligament, she has been able completely to extend the knee, a feat which she has been unable to accomplish for more than six months.

I have had similar success with other cases of osteo-arthritis and climacteric arthritis. There are generally to be found a series of painful spots about the internal lateral ligament and around the patella. Pressure on such a spot not only causes pain, but often a twitch can be seen to occur in one of the muscles moving the knee-joint. As your correspondent points out, it may be necessary to repeat the injections, but my experience has been that the increased range of movement permitted by this anæsthesia improves the blood-supply to the peri-articular structures and automatically massages the affected area.—I am, Sir, yours faithfully,

Bristol, March 29th, 1932. FRANK BODMAN.

ANÆMIA: A CORRECTION.

To the Editor of THE LANCET.

SIR,—I trust you will allow me to make an important correction to your leading article on anæmia, in which you refer so kindly to my Goulstonian lectures. The discovery that the gastric juice in simple achlorhydric anæmia contains the ferment which will generate from beef the substance which is missing in pernicious anæmia was made by Castle and co-workers (*Amer. Jour. Med. Sci.*, 1930, clxxx., 305, and 1931, clxxxii., 741). Dr. S. J. Hartfall and I have merely confirmed Castle's pioneer observations.

I am, Sir, yours faithfully,

Wimpole-street, W., March 26th, 1932. L. J. WITTS.

PRINCESS BEATRICE HOSPITAL.—The annual meeting of this hospital was held recently in the new building in Richmond-road, Earl's-court, which has been erected on the site of the old Kensington, Fulham, and Chelsea General Hospital. The building, which has 78 beds and two theatres, is now ready for the reception of patients; it is heavily in debt. Last year out-patients' attendances exceeded 39,000, an increase of more than 3000.

WOLVERHAMPTON ROYAL HOSPITAL.—The annual report describes 1931 as "the most difficult in the history" of this hospital. The daily average of occupied beds increased from 164 to 180; there were 5762 in-patients, 45,505 out-patients, and 7622 operations. The average stay at the General Hospital was 15·46 days, an increase on the last two years. The cost per head was £6 13*s.* 7½*d.*, also a slight increase; the cost per bed occupied was £157 14*s.* 4½*d.*, compared with £175 10*s.* 9*d.* the previous year, and £163 15*s.* 11*d.* in 1929. At the Women's Hospital the average stay was 14·2 days, a decrease on the previous year; the cost per head was £8 2*s.* 5*d.*, also a decrease; and the cost per bed occupied was £208 13*s.* 8½*d.*, compared with £209 2*s.* 11*d.* the previous year, and £225 4*s.* 5½*d.* in 1929. The accounts of the General Hospital show a deficit of £9807 and of the Women's Hospital of £6860. Legacies, however, amounted to more than £30,000, and great hopes are based upon the contributory fund started six months ago. With the exception of poor persons, all non-members of the contributory association will be called upon to pay a maintenance charge.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

EASTER ADJOURNMENT.

THE House of Lords and the House of Commons both adjourned for the Easter recess on Thursday, March 24th. Among the measures to which the Royal Assent was given by Royal Commission was the Dangerous Drugs Act. The House of Lords will reassemble on April 12th and the House of Commons on April 5th.

DANGEROUS DRUGS BILL.

In the House of Commons on Monday, March 21st, the Dangerous Drugs Bill passed through Committee and was read the third time without amendment.

PUBLIC HEALTH (CLEANSING OF SHELL-FISH) BILL.

On the motion for the second reading of the Public Health (Cleansing of Shell-fish) Bill,

Mr. ROSBOTHAM said that this was a Bill to give local authorities power to lend money for the erection of tanks for the cleansing of shell-fish. Very valuable beds of mussels existed on the banks of several of our rivers, in particular the River Ribble. They were worth several thousands of pounds but were being closed, owing to Public Health Orders, so far as human consumption was concerned. The tanks would provide a very simple method of cleansing the fish. The Ministry of Health had conducted experiments over a series of years and those experiments had been very successful. Now that there was a 10 per cent. duty on foreign mussels it was all the more important that this Bill should be passed.

The Bill was read a second time.

LOTTERIES FOR CHARITIES.

In the House of Commons on March 22nd, Sir W. DAVISON asked leave to introduce a Bill to authorise the raising of money by means of lotteries for charitable, scientific, and artistic purposes, or for any public improvement or other public object, under conditions approved by the Home Secretary. He said that when he introduced a Bill last year he confined its scope to the provision of funds for hospitals on the same lines as the sweepstakes in the Irish Free State. In view of representations made to him he had drawn the present Bill on somewhat wider and simpler lines, although British hospitals would still be within its scope and could take advantage of it should they so desire. It was interesting to note that of the 180 members of the House who voted against the Bill which he introduced last year some 130 had since lost their seats. He did not say that they had lost their seats solely because they voted against his Bill, but that they represented a type of mind not acceptable to the majority of their fellow citizens. Clause 1 of the Bill provided that notwithstanding anything to the contrary in any Act of Parliament or rule of law, it should be lawful for the governing body or trustees of any charity, and any trustees or body of persons appointed solely and mainly for the purpose of raising money for any scientific or artistic purposes, or for carrying out public improvements, to hold, with the approval of the Secretary of State, a lottery to raise money for such charity, purposes, or object. Clause 2 provided that no lottery should be held except in pursuance of a scheme sanctioned by the Secretary of State and for the charity or object named in the scheme. Clause 3 set out certain conditions and regulations, but did not preclude the Secretary of State from making others if he thought fit. The Bill would not apply to Northern Ireland. If it was thought that the scheme of the Bill was too wide, or that it should be confined to hospitals, as his last Bill was, or that the number of lotteries in any one year should be fixed, that could be easily done in committee. There was nothing inherently vicious or demoralising in holding a lottery. State lotteries were held in this country for many years. Queen Elizabeth was the first patron of a State lottery, which was held in this country for the repair of the havens of the realm and for public works. The penal legislation under which the Home Office now acted was passed in 1834, nearly 100 years ago. Under that, the Home Office searched travellers arriving at Holyhead, they opened private letters and even letters from solicitors to their clients. This legislation was not passed with any idea of stopping a vicious or immoral practice but to protect the State lotteries from unfair competition by private lotteries and lotteries organised abroad. From the Irish sweepstakes just concluded the hospitals received £841,000. Previously they had received over £2,000,000, and in all they had now had practically £3,000,000. How much sickness and suffering in this country might have been saved if this money had been kept here! A recent visitor to Dublin, who saw the hospital drum there, stated that when he arrived at Euston on his return he saw in the street a medical student beating a drum with a procession behind him, asking for alms for a London hospital. Which of the two methods was the most dignified? Another hospital appeal issued recently said that 1000 patients were waiting for beds owing to lack of funds. Those funds could be provided by a lottery. Of the £3,000,000 received in Ireland, over £2,000,000 came from this country. No one imagined that if lotteries for hospitals were established in this country they would maintain the hospitals; the hospitals wanted millions a year. They would, however, provide funds for urgently needed equipment and those beds which were urgently needed at the present moment.

Mr. HOPKIN MORRIS asked the House to reject the motion for the introduction of the Bill. He said he agreed that the betting law was in an anomalous position, and said that a far-reaching inquiry into the whole question was required. He agreed that hospitals were worthy objects, but were hon. Members going to support them by questionable means? The amount raised by bequests, subscriptions, savings associations, and paying patients for the voluntary hospitals in this country last year was between £13,000,000 and £14,000,000. That was in a year of acute depression. Of that sum some 50 or 60 per cent. came from voluntary contributions. What amount of sweepstakes would be required to assure an income equivalent to that amount? He was taking the figures of a very competent hospital accountant who said that it would require three sweepstakes a year each yielding £10,000,000; a total of £30,000,000 a year. If they took the figures of the Irish sweepstakes and assumed—and it was a big assumption—that there would be treble the number of subscribers in this country that would yield approximately £15,000,000, leaving a deficiency of £15,000,000. The testimony of the chairman of the Royal City of Dublin Hospital was to the effect that the annual subscribers were withdrawing their funds on the ground that they were no longer needed, that paying patients, generally working-class men and women, were objecting to pay anything for treatment, that business firms were refusing to pay anything, and that people were not now leaving bequests for hospitals. The Governor of the Charing Cross Hospital stated last year: "Speaking for myself and this hospital we will have neither part nor lot in any such scheme, and our reasons are not simply moral ones, though they weigh very considerably. Looking at it from a business standpoint we believe the gain would be outweighed by the loss." This was clearly a case where there should be an inquiry first. They could not put these charitable institutions, depending as they did on the moral goodwill of men and women, on the basis of chance. (Cheers.)

Leave was given to introduce the Bill by 176 votes to 123—majority 53. Sir W. Davison then brought in the Bill amid cheers and it was read a first time.

HOUSE OF COMMONS.

TUESDAY, MARCH 22ND.

Small-pox Statistics.

Mr. GROVES asked the Minister of Health whether the statistics of small-pox cases published in the epidemiological report of the health organisation of the League of Nations were supplied by his department; and whether the statistics of small-pox deaths were also supplied.—Sir E. HILTON YOUNG replied: The official returns of the Registrar-General and other official documents relating to small-pox cases and small-pox deaths in England and Wales are regularly supplied by my department to the Health Organisation of the League of Nations and are available to that organisation in the preparation of its epidemiological reports.

Miners' Nystagmus.

Mr. PARKINSON asked the Secretary for Mines the number of cases of miners' nystagmus which had occurred in the Lancashire coalfields for 1927, 1928, 1929, 1930, and 1931, respectively.—Mr. ISAAC FOOT replied: The number of cases of nystagmus in Lancashire and Cheshire certified under the Workmen's Compensation Act during the years in question was in 1928, 319; in 1929, 302; and in 1930, 306. This information is not available for 1927 and the returns for 1931 are not yet completed.

Duties on Imported Milk.

Sir CHARLES CAYZER asked the Secretary to the Treasury what proportion of the milk imports into this country were subject to the new duties imposed under the Import Duties Act on the basis of the trade figures for 1931.—Major ELLIOT (the Financial Secretary to the Treasury) replied: It is estimated on the basis of the Trade Accounts for 1931 that the general ad-valorem duty will be paid on approximately 22 per cent. of the milk imports.

Sir CHARLES CAYZER asked the Secretary to the Treasury whether his attention had been called to the fact that duty was not being charged under the Import Duties Act on imported sweetened condensed milk because such milk was already taxed on its sugar content; and for what reason this decision was reached, in view of the fact that double duties in respect of the Abnormal Importations (Customs Duties) Act and under legislation previous thereto were being charged on a number of other imported manufactured articles.—Major ELLIOT replied: There is no analogy between the Abnormal Importations Act and the Import Duties Act, since the object of the former was expressly to prevent the influx of certain goods into this country. I may point out that it is open to the Advisory Committee to consider the case of any composite goods and to recommend additional duties in respect of them.

Abortion.

Lieut.-Colonel MOORE-BRABAZON asked the Minister of Health whether he would consider the present state of the law with regard to the practice of abortion under the Act of 1861 with a view to amending that Act.—Sir T. INSKIP (Attorney-General) replied: I am at all times happy to consider the state of the law with regard to any subject, but I am not at present satisfied that the law concerning this matter requires amendment.

WEDNESDAY, MARCH 23RD.

Purity of Milk Supplied to the House.

Mr. GLOSSOP asked the Chairman of the Kitchen Committee whether he was aware that milk supplied in the members' tea room on Wednesday, 16th instant, was found on analysis to contain 2,000,000 bacteria per c.cm. and bacillus coli present in 1/1000 c.cm.; that the lowest standard graded milk was not allowed to contain more than 200,000 bacteria per c.cm. and no bacillus coli whatsoever; and what steps he proposed to take in order to safeguard the health of members who consumed milk with their tea.—Sir J. GANZONI (for the Chairman of the Kitchen Committee) replied: All milk provided by the Kitchen Committee is pure full cream, pasteurised milk, of the first quality. It is delivered in the original ten-gallon cans, sealed and fastened, from the same dairyman who has supplied us for over 20 years. As the Committee had no notice from the hon. Member that a sample was being taken on Wednesday, March 16th, until the question appeared on the Order Paper on Tuesday, March 22nd, they can have no knowledge as to whether it was properly taken, if in a perfectly sterile vessel, kept at a suitable temperature, and analysed immediately afterwards. The Committee take every precaution to secure the purity of the supply.

Mr. GLOSSOP: Is the hon. Member aware of the very unsatisfactory results of the test which has been carried out on rats after feeding them with pasteurised milk, and in view of the fact that this House contains so many young members for whom milk should still form an essential part of the diet. (Laughter.)

The SPEAKER: The hon. Member must concentrate his question in shorter form.

Fatal Aircraft Accidents.

Mr. SIMMONDS asked the Under-Secretary of State for Air the number of persons killed in this country during the last three years whilst flying in aircraft bearing a British-validated foreign certificate of air worthiness; and what proportion of these deaths was due to mechanical or structural failure.—Sir P. SASSOON (Under-Secretary of State for Air) replied: During the last three years there has been one fatal accident in this country to an aircraft with a British-validated foreign certificate of air worthiness; this accident involved six deaths and was due to structural failure.

Mr. SIMMONDS: Does not the Under-Secretary think that this matter should be investigated, because these validated certificates tend to bring our own certificates into disrepute?

Sir P. SASSOON: There has only been one accident in three years, and the whole report upon it has been published.

THURSDAY, MARCH 24TH.

Health and Pensions Insurance.

Sir R. ASKE asked the Minister of Health whether he was aware that, owing to the unemployment that had existed for years in shipbuilding and other industrial areas, numbers of men were being disqualified for sick benefits and contributory pensions; and whether he would consider the desirability of introducing legislation to reduce the number of qualifying contributions in such cases until more work is available. —Sir E. HILTON YOUNG replied: It would appear that my hon. friend has been misinformed, inasmuch as under the existing law the health and pensions insurance of persons who are unable to secure work is maintained so long as they can prove that they are genuinely unemployed, and provision is also made to secure that an insured person shall not suffer loss or reduction of benefits as a result of arrears due to unemployment. In these circumstances I cannot see any necessity for amending legislation on the lines suggested.

Police Witnesses and Accident Cases.

Captain MOSS asked the Home Secretary if he would reconsider the decision communicated to chief constables on May 27th, 1929, whereby chief constables were authorised to demand a payment as a condition of permitting a police constable, who had witnessed an accident, to be interviewed and a note, proof, or precognition of his evidence to be taken with a view to tendering him as a witness in a civil claim for damages.—Sir H. SAMUEL: No, Sir; the amount of police time occupied by interviews of this nature fully justifies the making of a charge.

Mr. MACQUISTEN: Does the right. hon. gentleman not see how that would injure the course of justice if a private citizen were not to do his duty unless paid in advance. Why should a policeman not do the duty of an ordinary citizen without being paid for it?

Sir H. SAMUEL: The police are not primarily concerned with civil litigation, and if the private parties to civil proceedings require police evidence and take up the time of the police it is right in the public interest that a fee should be paid. If in any particular case hardship is involved on account of poverty the fee is waived. If a policeman is summoned as a witness he has to attend in the ordinary course, but for interviews beforehand with solicitors and so forth a public servant, such as a policeman, is entitled to have his services charged for in the interests of the public purse.

Medical Treatment of School-children.

Mr. GROVES asked the President of the Board of Education what provision was made by his Department to grant compensation to any school-child who met with permanent physical injury whilst attending for treatment under the instruction of the local education authority's school medical service.—Mr. HERWALD RAMSBOTHAM (Parliamentary Secretary to the Board of Education) replied: There have been very few cases indeed in which children have received permanent physical injury as a result of medical treatment received under arrangements made by local education authorities. There have been a few cases in which local authorities, while not admitting legal liability, have made payments as a result of complaints of this character, and the Board of Education have recognised their expenditure for the purposes of grant. The Board have no power themselves to grant compensation in such cases.

THE INTERNATIONAL CONGRESS OF SURGERY.

MADRID, MARCH 14TH–19TH.

(FROM A CORRESPONDENT.)

THE ninth Congress of the International Society of Surgery, held in Madrid, was in every way a notable success. The President of the Republic and several members of his government were made members of honour for the occasion, while the local arrangements were carried out by a committee presided over by the venerable Prof. Sebastián Recaséns, whose energy and driving force had obviously done much to make the congress possible. The occasion was attended by members from some 30 countries, including such far distant places as Finland, Poland, Japan, America, and New Zealand.

The British members were only five and of this small band Dr. Macdonald was a resident of Huelva in Spain. The United States of America sent three members (Drs. Elsberg and Lilienthal, of New York, and Mixter, of Boston). But the congress generally was thoroughly representative and was well patronised, about 300 members being present. The greater number came from Spain, but there were many from France and Italy, while for the first time since the war, Germany sent delegates, and the attendance of Prof. Sauerbruch, of Berlin, added much to the vitality of the meetings. The Government of the Republic and the municipality of Madrid did everything possible to make the congress a success and placed the Senate House at the disposal of the members, and here all the principal meetings were held.

Prof. F. de Quervain, of Berne, was the president of the congress, and he was ably supported by Prof. Verhoogen, of Brussels, president of the society. The vice-president, Prof. Recaséns (Madrid), the members of the international committee, and the energetic secretary of the society, Dr. L. Mayer (Brussels), all played a part in carrying through a wonderful programme. The Senate House was packed for the inaugural ceremony at 11 o'clock on Tuesday, March 15th, and the occasion was notable because of the attendance of the President of the Republic, His Excellency Alcalá Zamora, who opened the congress, and in welcoming the members to Spain took occasion slyly to refer to the bloodless operation which had recently been carried out in his country. The mayor of Madrid also spoke and gave a warm welcome on behalf of the city over which he presides. Dr. L. Mayer, the secretary-general, gave an admirable report of the work of the society, speaking first in Spanish and continuing in French, and Profs. Verhoogen and de Quervain also addressed the assembly.

SCIENTIFIC SESSIONS.

The scientific work of the congress began immediately afterwards. The first question was the Surgery of the Œsophagus and reports were presented by Gregoire (Paris), Zaaijer (Leiden), Lusena (Genoa), Cardenal (Madrid), and Grey Turner (Newcastle). No really new ground was broken; everyone was pessimistic about the treatment of carcinoma and this was emphasised by Sauerbruch who took part in the subsequent discussion. Nevertheless it was admitted by several of the speakers that the alternatives had been almost equally disappointing and that the methods of radical operation could not be entirely discarded in the hope that some practical and successful method might yet be evolved. Grey Turner spoke of the pull-through method and expressed the belief that at some future congress fresh hope would dawn on this dismal subject. Several speakers referred to the diminishing frequency of œsophageal conditions amenable to major surgery because of the earlier diagnosis and treatment of the causative lesions. Each day the scientific discussions were resumed in the afternoons at 3.30 and continued until 5.

The second question, discussed on Wednesday, was the Treatment of Non-Tuberculous Suppuration of the Lung. Among the reporters were Sauerbruch (Berlin), Lilienthal (New York), Baumgartner (Paris), Martin Lagos (Valencia), Ascoli (Rome), and others, and no less than 29 speakers had signified their intention of joining in the subsequent discussion. Fortunately, perhaps, many of these were not present or the discussion would have been endless. None the less it is disappointing to read distinguished or interesting names on the order of the day, only to find that they are not in attendance when called upon.

The third question was The Diagnosis and Surgical Treatment of Tumours of the Spinal Cord. Notable communications were made by Prof. Beriel, of Lyons, who came by invitation to address the congress on the question of diagnosis, by Elsberg, of New York, who spoke from his very large experience of over 200 cases, by de Martel, of Paris, and Jurasz, of Posen. In the subsequent discussion, Prof. A. Young (Glasgow), Mixter (Boston), and Lambert Rogers (Cardiff), among others, spoke. The caution urged in the use of lipiodol was notable, and Elsberg said that in a long series of cases it had only been used in 5 per cent. Prof. Young drew attention to the difficulties associated with multiple and with metastatic tumours. Leriche urged the claims of osteoplastic laminectomy, especially in the cervical region, and Lambert Rogers, in a lucid communication, endeavoured to enumerate the factors which had a bearing on the question of prognosis after operation. The last question, discussed on Friday, was Recent Progress in Anæsthesia. In this a careful paper was presented by Ishikawa (Japan) whose investigations on local anæsthesia in animals largely proved the well-known conclusions reached by Lennander, of Upsala, years ago. The report by Jurasz (Posen) was careful and complete, while that by Anschütz (Kiel) on Avertin was moderate in tone and helpful.

The scientific sessions were very well attended, and it was remarkable how interest was sustained throughout despite the polyglot assembly. Of course there was the usual difficulty of restraining ardent speakers to something like a reasonable time limit, and this reached a climax when one member, who was allotted 5 minutes, continued for 25! Copies of many of the papers were distributed at the congress, each with a short summary in each of the six official languages. Eventually, these, with others, will be issued in a volume or volumes of 2000 pages which will be distributed gratis to each member.

OTHER ACTIVITIES.

In the anterooms of the Senate House there was an exhibition of surgical instruments, books, &c. Among these was a notable exhibit from the National Surgical Instrument Factory which has been established at Toledo, truly an example of the conversion of bayonets into ploughshares. On Thursday and Friday mornings at 9 o'clock operative sessions were arranged at the hospital clinic of the faculty of medicine, and it was an inspiration to see many of the surgeons whose names are bywords in Europe riveted on the work in hand, though probably this critical audience had an appreciable effect on the operators. In another hospital, Prof. Recaséns also conducted an operative session.

On Wednesday morning the members of the congress paid a visit to the University City which is being erected in the suburbs, and where in a large settlement accommodation of every kind is being provided for 2000 students of the medical faculty. This includes not only all the requisites for teaching, laboratories, &c., but residential quarters, and an enormous stadium. Social functions were innumerable and commenced with a reception, on the night of our arrival at Madrid, at 10.30, which for that city, is quite a reasonable hour. At this and all similar functions an ample midnight meal was provided, euphemistically called "lunch," which is a very popular word on the menus in the capital of Spain. This was invariably followed by dancing, which was carried on until 2 or 3 o'clock in the morning. Those of us who were expected to be present at some academic function on the following days, commencing not later than 9 o'clock, could well understand the sentiments of Sancho Panza when he declared "thrice blessed be the man who first invented sleep." Other social functions included a reception at the National Palace by the President of the Republic, a reception by the mayor at the town hall, and a gala performance at the theatre. An excellent entertainment and reception was provided by the president of the congress, de Quervain, where we were introduced to a wonderful exhibition of Andalusian dancing and music. This and other entertainments innumerable were brought to an end with a final "Banquet of Closure" which was an enormous affair which everybody with their ladies attended. Here the speeches were limited, for the banquet itself did not commence until 10 o'clock, and if, as at other congresses, every delegate had been expected to reply for his country, then we must have gone on till the following day at breakfast time. But the occasion was not wasted by our hosts, for the Minister of Public Instruction and again the Mayor of Madrid, took the opportunity of doing a little propaganda on behalf of the new régime.

Perhaps the most pleasant part of all the congress was the informal meeting of friends, and, indeed, this sort of thing is probably the most useful function of any congress of the kind, for it is a great privilege to meet in the flesh men whose surgical names are known the world over, to renew friendships, and to make new ones. Nothing is more likely to promote international good feeling, for truly surgery knows no frontiers, and one soon learns that there are caballeros in every land. It is a great pleasure to pay a tribute to the cordiality with which the congress was treated on all hands, and those who took part must feel grateful to Prof. Recaséns, the president of the local committee, and to his collaborators, and to Prof. Lozano, of Saragossa, whose privilege it was to first issue the invitation for the congress to visit Spain.

The next meeting has been fixed to take place in Egypt in 1935. Prof. Anton von Eiselsberg, of Vienna, is president-elect, and the following are the subjects already selected for discussion: (1) The Surgery of the Parathyroids; (2) The Non-Malignant Diseases of the Colon; (3) The Lumbar Sympathetic. In addition there will be a fourth subject to be chosen by the executive, and this will probably deal with some aspect of tropical disease.

OBITUARY

ROBERT MATTHEW BRONTË, L.R.C.P., L.R.C.S.I., D.P.H.

Dr. Robert Matthew Brontë, whose death announced in our issue of last week, was a northe Irishman, born at Armagh and educated at t Royal School there. He commenced his profession career in the old-fashioned way as an apprentice a medical man in Inniskillen, and completed medical course in Dublin, qualifying with the doul diploma in 1907, while in the following year he obtain the D.P.H. of the Irish College of Surgeons. made no attempt to obtain any academic distinctio but immediately showed his practical interest subjects familiarity with which gave him afterwar his public position. He became a demonstrator the Royal College of Surgeons and held private classe which were very popular among students enteri for examinations. He lectured on public heal and familiarised himself with the analytical side the chemistry required, while he also assisted at o time the professor of chemistry in the College. Th led to his holding the appointment in Ireland Crown Analyst, a post which he held until he came England ten years ago and went to live in Harro He became here pathologist to the Harrow Hospit a post which he combined with that of pathologi to the Samaritan Free Hospital for Women. showed himself particularly interested in all questio of forensic medicine and this led to an increasi association with the coroner's court in the Weste District and elsewhere. He was frequently considerable help to coroners who, in Lond especially, find considerable difficulty in getti assistance in the performance of post morte Most of the pathological specialists in London ho full time appointments connected with the teachi schools or under the L.C.C. and are not availab to help coroners in this direction. Dr. Bron undoubtedly provided the London coroners wi expert assistance on many occasions, but he had official connexion whatever with the Home Offic and the description of him as the "Home Offi expert," frequently used in newspapers, placed hi occasionally in an unpleasant situation with t Government Department. He was never invited assist the Crown in medico-legal work except in cas where he had already performed the post-morte examination at the instance of the coroner, when, course, he gave his evidence as any other medic practitioner would have done. He was concerned many causes celèbres and proved himself a goo witness. In big criminal trials it is always importa that the defence should have expert legal advi and Dr. Brontë acted in this capacity on man occasions. Although in the two most sensational tria with which he was concerned he failed to shake t belief of the juries in the guilt of the accused, knowledge of pathology was considerable, and he w making good use of his experience when he died March 22nd, at the comparatively early age of 52.

THE LATE DR. G. B. HILLMAN.

THE following appreciative note upon Dr. G. Hillman, whose death was chronicled in THE LANCE last week, reaches us from Dr. Wardrop Griffith:

"By the death of Dr. G. B. Hillman a great loss h fallen upon the West Riding, for Wakefield has lo its Member of Parliament, a justice of the peace, an one of its former mayors; the Local Medical and Panel Committee is deprived of its greatly respected chairman; and a large circle of personal friends and patients will have to lament the passing of one in whom they had learned to place great trust and who stood very high in their affection. During his 30 years at Castleford he conducted a large general practice and he stood high, and most deservedly so, in the trust of his patients. In his public work he was most painstaking and conscientious, and everyone felt that when he expressed an opinion it was the result of careful thought. In no capacity did his work command the respect of his professional brethren in a greater degree than in his conduct in the chair of the Local Medical and Panel Committee of the West Riding of Yorkshire. Invariably courteous and patient, he encouraged the fullest expression of opinion on the part of all the members, but with tact he seemed to guide the meeting in the right direction and to secure a large measure of agreement in many a difficult and controversial matter."

A service was held at Holy Trinity Church, Wakefield, before the interment at Castleford, and this was largely attended by representatives of various public bodies and by a large number of medical men from the wide area of the West Riding.

MEDICAL NEWS

University of Leeds.

At recent examinations the following candidates were successful:—

M.D.

Mildred I. Ealing.

CH.M.

A. B. Pain.

FINAL EXAMINATION FOR M.B., CH.B.

Part I.: F. Badrock, G. W. Blomfield, Kathleen S. Bruce, F. L. Cane, Y. Carasik, C. D. Clark, O. E. Fisher, J. Gibson, L. Goldwater, S. I. Leshinsky, Vida L. Liddell, E. Lodge, K. O. Milner, J. T. Rhodes, R. T. Rushton, W. Sharp, D. Thackray, W. H. Tod, N. Wood, and W. Zemsky. *Part II.:* H. Agar, Doris B. Brown, E. Gledhill, Gwendolen Harrison, H. Hart, F. R. W. Hemsley, Ruth Hooton, A. G. James, E. A. James, F. C. Leach, I. Macpherson, J. Q. Mountain, I. Rosenberg, L. W. Russell, and M. Shankhla. *Part III.:* E. Gledhill (First Class Honours), Doris B. Brown (Second Class Honours), H. Agar, Gwendolen Harrison, H. Hart, Ruth Hooton, A. G. James, I. Macpherson, J. Q. Mountain, I. Rosenberg, L. W. Russell, C. K. Shain, and M. Shankhla.

FINAL EXAMINATION FOR L.D.S.

Muriel Barnby, G. L. B. Fillingham, and J. Jackson.

D.P.H.

J. F. Galpine.

D.P.M.

F. E. Kingston.

Royal College of Surgeons of Edinburgh.

The following candidates, having passed the requisite examinations, have been granted the diploma of L.D.S.:—

Maurice Goldfar, G. A. Rodger, R. C. Stanger, R. A. F. Murdoch, William Arbuckle, K. P. Whaley, and William Elgey.

Progress of Cremation.

Presiding at the annual meeting of the Cremation Society in London on March 16th, Mr. Murray Phelps said that when it was remembered that every year something like half a million bodies were buried in our midst, it was certainly remarkable that no legislative measure of reform had been attempted since the Burial Act of 1885. One cemetery in the heart of London, which was opened in 1810, and in which over 155,000 burials had taken place in the following half century, was still being used for interments. Public money which could be more usefully employed was being spent in the wasteful acquisition of large areas of valuable land for purposes of burial in and around large centres of population. With a view to bringing cremation within the reach of wider sections of the population, nearly every cremation authority had adopted a reduced scale of charges for persons insured under the National Health Insurance scheme and their dependants. The annual report showed that there were now 22 British crematoria, and that the number of cremations had increased from 4533 to 5195 during the year. This figure, however, represented only 1 per cent. of deaths, which showed how little progress cremation had yet made here as compared with Central Europe and Scandinavian countries.

University of Liverpool.

Dr. Herbert Roaf, professor of physiology in the London Hospital Medical College, has been invited to accept appointment to the George Holt chair of physiology in the University, in succession to Prof. J. S. Macdonald, who will retire at the end of the present session.

Osler Club.

At a meeting of this club on March 24th, Sir Robert Philip gave an address entitled *Robert Koch's Discovery of the Tubercle Bacillus: Some of its Implications and Results.* A vote of thanks was proposed by Dr. W. G. Willoughby, president of the British Medical Association, and seconded by Dr. William Stobie, mayor of Oxford.

Royal Society of Arts.

Prof. J. C. Drummond will give three Cantor lectures before this society (John-street, Adelphi, London, W.C.) at 8 P.M. on Mondays, April 18th and 25th, and May 2nd. His subject will be Recent Researches on the Nature and Functions of Vitamins.

Paddington Medical Society.

At a meeting of this society on April 12th a debate on a State Medical Service will be opened by Mr. Somerville Hastings and Sir Ernest Graham-Little. Dr. G. C. Anderson (deputy medical secretary, British Medical Association), Dr. A. Welply (secretary, Medical Practitioners' Union), and Dr. C. L. Batteson (secretary, London Panel Committee) have promised to speak. The hon. secretary's address is 23, Westbourne Park-road, London, W. 2.

Hospital Libraries.

Dr. Barrie Lambert, chairman of the central public health committee of the L.C.C., will take the chair at a meeting to be held at the County Hall, Westminster Bridge, S.E., at 5.30 P.M. on Friday, April 29th, to discuss Hospital Libraries and Librarianship. The speakers will include Lord Gorell, Dr. H. A. Powell, Dr. W. J. T. Kimber, and Mr. C. Hagberg Wright, LL.D. Further information may be had from the organising secretary, British Red Cross and Order of St. John Hospital Library, 48, Queen's-gardens, W.2.

Medical Advisory Board for Blind Masseurs.

The Association of Certificated Blind Masseurs has formed a medical board to advise on the extension of training of blind masseurs and masseuses. It will consist of Dr. L. Danyers Bailey, Dr. C. C. Worster-Drought, Dr. F. D. Howitt, Dr. W. Kerr Russell, Mr. P. Jenner Verrall, Mr. A. Mace (representing St. Dunstan's), and Mr. P. L. Way (representing the council of the Association and the Massage School of the National Institute for the Blind). The secretary is Mrs. F. Chaplin Hall.

Demonstrations of Contraceptive Technique.

The Society for Constructive Birth Control and Racial Progress inform us that at 2.30 P.M. on Wednesday, April 6th, demonstrations of contraceptive technique will be given at their clinic to medical practitioners and senior medical students who will be given an opportunity of practising under tuition a variety of methods. Application should be made to the hon. secretary of the society at 108, Whitfield-street, London, W.1.

Dr. Alfred Cox Testimonial.

At the invitation of Sir Arthur Cope, a few members of the executive committee of the Fund attended at his house to see the portrait painted of Dr. Alfred Cox before its transfer to the Royal Academy on April 4th next. The opinion was unanimous that Sir Arthur Cope had caught, in a pleasing manner, the personality of Dr. Alfred Cox, and this was expressed to him on behalf of those present by Sir Ewen Maclean, chairman of the executive committee, and endorsed by others present.

Worthing Hospital.

The report of this institution, presented at the annual meeting on March 21st, showed an increase alike of in-patients and out-patients. Referring to the fact that more work is placed on the honorary medical staff, the governors said that "if only the public were more fully aware of the time and skill voluntarily given by the medical staff, we feel sure it would make a greater effort to supply the funds required to back it up." The report showed that it was for want of funds that only 67 of the 78 beds could be properly staffed and used; and it was considered that with a population of over 50,000 people, there should be more than 700 annual subscribers. Compared with deficits of £1688 and £1325 in 1929 and 1930 respectively, the year's working showed an adverse balance of only £65; this was due to various special efforts on behalf of the hospital and to the exercise of the strictest economy.

Medical Diary

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Tuesday, April 5th.—5.30 P.M., Orthopædics. (Cases at 4.30 P.M.) Mr. W. H. Ogilvie: 1. Fracture of Cervical Spine. 2. Tuberculous Disease of Pubis. Mr. H.J. Seddon: 3. Successful Arthroplastics in Old Case of Still's Disease. Mr N St J Burton : 4. Pathological Specimen of ith. Mr. E. P. Brockma of Case Shown Previously. Dr. E. Henrietta Jebens: 6. Myeloma of Tendon Sheath. Mr. R. C. Elmslie: 7. Traumatic Dislocation of the Hip Followed by Coxa Plana. Other cases will be shown.

Wednesday.—5 P.M., History of Medicine. Dr. Ernest Jones: Medical, Theological, and Popular Views Concerning the Nightmare. A discussion will follow in which Dr. William Brown, Prof. C. G. Seligman, and others will take part. Dr. R. O. Moon (for Dr. B. Farrington): The Preface of Andreas Vesalius to the De Fabrica. 8.30 P.M., Surgery. Paper: Mr. R. E. Kelly: The Use of the Cinematograph in the Teaching of Surgery. Films will be shown by Mr. Kelly and Mr. W. H. Ogilvie.

Thursday.—8 P.M., Tropical Diseases and Parasitology: Medicine. Discussion: The Megalocytic Anæmias of Tropical and Non-tropical Countries. Openers: Dr. N. Hamilton Fairley, Dr. Lucy Wills, Dr. G. W. Goodhart, and Dr. L. J. Witts. The discussion will be preceded by an Illustrative Demonstration by Dr. Hamilton Fairley. Members of the Sections of Obstetrics and Gynæcology and Pathology are specially invited to attend.

Friday.—5.30 P.M., Clinical. (Cases at 4.30 P.M.)

WEST KENT MEDICO-CHIRURGICAL SOCIETY, Miller General Hospital, Greenwich.

Friday, April 8th.—8.45 P.M., Mr. A. Walker: Danger Signals in Midwifery Practice.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos-street,

Friday, April 8th.—8.30 P. : Toxic Jaundice and Discussion.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, W.6.

.—10 A.M. to 1 P.M., Gynæcological Wards, Genito-Urinary Operations, Skin Department. 2 to 4 P.M., Operations, Surgical Wards. Medical, Surgical, Gynæcological, and Eye Out-patients. 4.15 P.M. (Lecture) Sir Henry Simson: The Management of Pregnancy and Labour.

Tuesday.—10 A.M. to 1 P.M., Medical Wards, Surgical Demonstration, Throat Operations, Dental Department. 2 P.M. to 4 P.M., Operations, Medical, Surgical, and Throat Out-patients. 4.15 P.M. (Lecture): Mr. Tyrrell Gray: Visceroptosis.

Wednesday.—10 A.M. to 1 P.M., Medical Wards, Children's Medical Out-patients, 2 P.M. to 4 P.M., Gynæcological Operations, Medical, Surgical, and Eye Out-patients. 4.45 P.M., Venereal Diseases Demonstration.

Thursday.—10 A.M. to 1 P.M., Neurological Out-patients, Fracture Demonstration. 2 P.M. to 4 P.M., Operations, Medical, Surgical, Genito-Urinary and Eye Out-patients. 4.15 P.M. (Lecture): Dr. Scott Pinchin: Diagnosis and Treatment of Pulmonary Tuberculosis.

Friday.—10 A.M. to 1 P.M., Medical Wards, Skin Out-Patients, Dental Department. 12 noon, Medical Lecture. 2 P.M. to 4 P.M., Operations, Medical, Surgical, and Throat Out-patients. 4.15 P.M. (Lecture): Dr. Redvers Ironside: Wasted Hands.

Saturday.—9 A.M. to 1 P.M., Throat Operations, Medical Wards, Surgical and Children's Medical Out-patients.

The lectures at 4.15 P.M., on Mondays, Tuesdays, Thursdays, and Fridays are open to all medical practitioners without fee.

ST. PETER'S HOSPITAL, Henrietta-street, Covent Garden, W.C.

Wednesday, April 6th.—3 P.M., Mr. C. Morson: Calculous Disease of the Urinary Tract.

ST. MARK'S HOSPITAL, City-road, E.C.

Thursday, April 7th.—4.30 P.M., Dr. Cuthbert Dukes: Classification of Cancer of the Rectum.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C.

Friday, April 8th.—4 P.M., Mr. F. W. Watkyn-Thomas: Points in the Acute Mastoid Operation.

SALFORD ROYAL HOSPITAL.

Thursday, April 7th.—Dr. C. J. Langley: Demonstration of Cardiac Cases.

MANCHESTER ROYAL INFIRMARY.

Tuesday, April 5th.—4.15 P.M., Prof. S. L. Baker: Post-mortem Findings in Cases of Cardiac Failure.

Friday.—4.15 P.M., Mr. J. P. Buckley: Demonstration of Surgical Cases.

ANCOATS HOSPITAL, Manchester.

Thursday, April 7th.—4.15 P.M., Dr. E. W. Twining: Radiology of Brain Lesions with Special Reference to Tumour.

ROYAL MATERNITY AND WOMEN'S HOSPITAL, Glasgow.

Wednesday, April 6th.—4.15 P.M., Prof. James Hendry: Obstetrical Cases.

Vacancies

For further information refer to the advertisement columns.

Altrincham General Hospital.—Jun. H.S. At rate of £120.

Aylesbury, Royal Buckinghamshire Hospital.—Res. M.O. At rate of £200.

Babies' Club, Chelsea.—Asst. M.O.

Belgrave Hospital for Children, 1, Clapham-road, S.W.—Two H.P.'s and One H.S. Each at rate of £100.

Birmingham, Dudley-road Hospital.—Gynæcologist and Obstetrician. £750.

Birmingham, Little Bromwich Hospital for Infectious Diseases.—Jun. Asst. M.O. £300.

Blackburn Royal Infirmary.—Fourth H.S. £150.

Bolingbroke Hospital, Wandsworth Common, S.W.—H.S. At rate of £120.

Bootle General Hospital, Derby-road, Bootle, near Liverpool.—Hon. Aurist.

nd Ear Hospital.—Jun. H.S. £150.

itution.—Asst. M.O. £250.

Bristol Eye Hospital.—Hon. Ophth. Surgeon.

Burton-on-Trent General Infirmary.—Jun. H.S. £150.

Cancer Hospital, —H.S. At rate of £100.

City of London of the Heart and Lungs, Victoria Par of £100.

Colchester, Essex County Hospital.—H.S. £175.

Connaught Hospital, Walthamstow, E.—Sen. Res. H.S. At rate of £150.

Derby, Derbyshire Hospital for Sick Children.—Res. H.S. At rate of £130.

Derb —H.S. for General Surgery. £150.

Dorc £650.

Exet –School Medical Inspector. £500.

Hastings, Royal East Sussex Hosp.—Jun. H.S. At rate of £100.

Hospital for Consumption and Diseases of the Chest, Brompton S.W.—H.P. At rate of £50.

Hospital for Epilepsy and Paralysis, Maida Vale, W.—Res. M.O. and H.P. At rate of £150 and £100 respectively Also Med. Reg. £100.

Hospital for Women, Soho-square, W.—Res. M.O. At rate of £100.

Ilford, King George Hospital.—H.S. At rate of £100.

Ipswich, East Suffolk and Ipswich Hospital.—H.S. and H.P. Each £120.

Johannesburg Hospital, South Africa.—Radiologist. £1500.

Lancaster R and Jun. Res. H.S.'s. £175 and £1

Leamington al Hospital.—Res. H.S. £165.

Liverpool, City Infectious Diseases Hosp.—Asst. Res. M.O. £250.

Liverpool, Hahnemann Hospital, Hope-street.—Res. M.O. At rate of £100.

Liverpool and District Hospital for Diseases of the Heart.—H.P. At rate of £100.

London Clinic and Nursing Home, 20, *Devonshire-place, W.*—Asst. House Governor.

London Hospital Medical College, E.—Hutchinson Triennial Prize, 1935.

Maidstone, Kent County Ophthalmic and Aural Hospital.—H.S. to Ear, Nose, and Throat Dept. At rate of £200.

Manchester, Ancoats Hospital.—Med. Reg. for Out-patient Dept.

Manchester Babies' Hospital, Burnage-lane, Levenshulme.—Med. Reg. £50.

Manchester, City.—Asst. Tuber. O. £650.

Manchester, Royal Children's Hospital, Pendlebury.—Res. M.O. At rate of £125.

Manchester, St. Mary's Hosps.—Three H.S.'s. Each at rate of £50.

Margate, Royal Sea Bathing Hospital.—H.S. At rate of £200.

'c Municipal Hospital.—Res. H.P. At

Greenwich-road, S.E.—Asst. Surgeon to Dept.

National Temperance Hospital, Hampstead-road, N.W.—Surg. Reg. 40 gns.

Northampton General Hospital.—H.S. At rate of £150.

Oldham Royal Infirmary.—H.S. £175.

Paddington Green Children's Hospital, W.—H.P. and H.S. Each at rate of £150.

Preston, Lancashire County Council.—Asst. County M.O. £800.

Preston, Wrightington Hospital, Parbold.—Jun. Asst. M.O. £200.

Royal Naval Medical Service.—Vacancies.

Salford, Hope Hospital.—Res. M.O. £400.

Salvation Army, Mothers' Hospital, Lower Clapton-road, Clapton, E.—Jun. Res. M.O. At rate of £60.

Southampton, Children's Hospital and Dispensary for Women.—Res. M.O. At rate of £100.

Southampton, Royal South Hants and Southampton Hospital.—H.S. At rate of £150.

Sutton, Surrey, Sutton and Cheam Hospital.—Res. M.O. At rate of £150.

Western Ophthalmic Hospital, Marylebone-road, N.W.—Sen. Res. and Jun. Non-Res. H.S. At rate of £150 and £100 respectively.

Worcester County and City Mental Hospital, Powick, near Worcester.—Sen. Asst. M.O. and Deputy Med. Supt. £600.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Meltham (Yorks.) and at Newtyle (Forfar).

NOTES, COMMENTS, AND ABSTRACTS

ASPECTS OF AMŒBIASIS.

MUCH valuable information is to be found in three papers [1] [2] [3] on amœbiasis which have reached us in reprint form since the appearance of our last annotation on the subject.[4]

Dr. P. H. Manson-Bahr [1] analyses 329 proven cases of intestinal amœbiasis treated by him between 1920 and 1931 in the Hospital for Tropical Diseases in London. These comprise acute and chronic examples of the disease, but as would be expected in tropical practice in this country cases of long duration and extreme chronicity predominate. This is especially so in this series which includes many ex-Service men and pensioners who sought treatment in the years immediately after the war.

TREATMENT.

Taking the various remedies seriatim, Manson-Bahr offers the fruits of his experience with each. He says of emetine injections: "Though the immediate effects of therapeutic injections of emetine are striking enough, yet this drug alone does not eradicate the infection." This is an important point which deserves more general recognition, especially abroad, if relapses in these cases are to be avoided. While emetine injections have a dramatic effect in acute and early stages of the disease, cases which are chronic and old-standing show poor results when so treated, and, more important still, those acute cases which were apparently "cured" initially often relapse within 12 months, or suffer from hepatitis and liver abscess later. There appears to be no relation between the total dosage and the relapse rate, for recurrences occur even in cases which have actually manifested signs of emetine poisoning. This point was investigated by Manson Rennie.[5]

With the introduction of emetine-bismuth-iodide (E.B.I.) therapy better results were obtained, but here again there were relapses in cases treated with this drug alone. Of Manson-Bahr's series of 134 cases thus treated 10 relapsed within 6 weeks, and 3 after as many as 9 separate 30-grain courses of E.B.I.—an indication of "emetine-fastness" on the part of *Entamœba histolytica*. Three cases were subsequently readmitted with liver abscess.

In 1925 a new drug called yatren was tried in this country. It consists of a close combination of iodine with oxyquinolin-sulphonic acid and 20 per cent. sodium bicarbonate, the iodine being so firmly combined that it is not split off by boiling, nor decomposed in the body. It can be administered in the form of pills or cachets, or by enema, the last being the method of choice when it is given in a 2½ per cent. solution. Between 1926 and 1931 no less than 181 patients were given combined E.B.I. and yatren treatment. The results of this combined method were such an advance on anything heretofore achieved that it will probably be many years before the method is superseded. Only two relapses were reported in this series, both of which yielded to a second course successfully.

Emetine per-iodide, a less nauseating drug, finds a place in the treatment of women and the more debilitated subjects, combined with yatren lavage. Stovarsol, so popular on the continent, is a doubtful specific but has a place in "after-treatment."

In conclusion, Manson-Bahr raises an important question in asking what criterion should be taken in assessing a definite cure. He is clearly right in believing that time alone can show, after testing various forms of treatment on a large number of *proven* cases. Active or cystic forms of *E. histolytica* were found in stools or sigmoidoscopic scrapings in all the cases he analyses.

AMŒBIASIS OF THE LIVER.

A second paper by Dr. Manson-Bahr and one by Mr. T. P. Kilner both deal with amœbiasis of the liver. Emphasising the extraordinary number and variety of signs and symptoms which may be manifested the former[2] recalls the dictum of Sir Patrick Manson that the diagnosis of liver abscess should always be carried at the back of one's mind. To quote figures, out of 45 cases only 3 showed any external bulging in the chest wall. In 40 cases the abscess was situated postero-superiorly in the right lobe—a fact which gave rise to discussion as to why that should be the site of election. In 45 per cent. of cases *E. histolytica* was found in the stools. The utility of radiography is emphasised, particularly in the demonstration on screening of elevation, fixation, or limited diaphragmatic movement on the affected side. "Doming" of the diaphragm was evident in one-third of the cases.

Manson-Bahr puts forward an interesting theory of the formation of liver abscess. He holds that it arises by the formation of necrotic foci in so-called hepatitis. Each focus consists of a "nest" of amœbæ, probably formed by fission of one original penetrating amœba, lying in the centre of each necrosing area. An early suppurative stage follows which may occur independently of active bowel infection. The necrotic tissue cytolised by the action of the amœbæ is sterile in a bacterial sense, and the amœbæ being still active are vulnerable to emetine in this stage, and the necrosis resolves without drainage. In the next stage the abscess cavity contains sterile pus and the lining walls active amœbæ, and therefore aspiration plus emetine therapy will do good. The final stage is one in which—possibly from lack of oxygen—the amœbæ are no longer active, the cavity is large, and secondary infection via the blood stream occurs. Open operation then becomes the only method of treatment, and later combined E.B.I. and yatren may be used to prevent reinfection from any uneradicated bowel infection.

Both writers describe the various measures of aspiration in detail, and Mr. Kilner[3] describes the technique of the open operation. He compares the uninfected amœbic abscess with the cold tuberculous abscess, and points out the similarity in treatment by aspiration in both conditions. Exploratory needling is the first step in surgical treatment, and the striking of pus also clinches the diagnosis. Once pus is found aspiration can be proceeded with and, if necessary, open operation performed.

For needling and aspiration local anæsthesia suffices as a rule, and causes no distress to the patient, even when as much as 1½ to 2 pints of pus are aspirated. Sometimes, however, pain is felt by the patient, and may be of two types. It may be either short, sharp, and due to needle pressure on a tightened liver capsule, or on the diaphragm, or persistent, cramp-like, and referred to the right shoulder. The latter type calls for general anæsthesia, and gas-and-oxygen apparatus should be kept close at hand.

Potain's aspirator is the best type to use when much pus requires aspiration, and with patience and care little blocking of the cannula by debris is found to occur. Where secondary infection is established the open operation with rib resection is essential.

These papers epitomise in plain language the most modern methods in treatment, both medical and surgical, of intestinal and hepatic amœbiasis. It remains for the medical profession in general to get these cases under treatment early. Fortunately it is beginning to be realised that amœbiasis may often be encountered in the temperate zone as well as in the tropics and subtropics,[4] and the condition is correspondingly less often overlooked.

NOTES, COMMENTS, AND ABSTRACTS

ASPECTS OF AMŒBIASIS.

Much valuable information is to be found in three papers[1, 2, 3] on amœbiasis which have reached us in reprint form since the appearance of our last annotation on the subject.[4]

Dr. P. H. Manson-Bahr[1] analyses 329 proven cases of intestinal amœbiasis treated by him between 1920 and 1931 in the Hospital for Tropical Diseases in London. These comprise acute and chronic examples of the disease, but as would be expected in tropical practice in this country cases of long duration and extreme chronicity predominate. This is especially so in this series which includes many ex-Service men and pensioners who sought treatment in the years immediately after the war.

TREATMENT.

Taking the various remedies seriatim, Manson-Bahr offers the fruits of his experience with each. He says of emetine injections: "Though the immediate effects of therapeutic injections of emetine are striking enough, yet this drug alone does not eradicate the infection." This is an important point which deserves more general recognition, especially abroad, if relapses in these cases are to be avoided. While emetine injections have a dramatic effect in acute and early stages of the disease, cases which are chronic and old-standing show poor results when so treated, and, more important still, those acute cases which were apparently "cured" initially often relapse within 12 months, or suffer from hepatitis and liver abscess later. There appears to be no relation between the total dosage and the relapse rate, for recurrences occur even in cases which have actually manifested signs of emetine poisoning. This point was investigated by Manson Rennie.[5]

With the introduction of emetine-bismuth-iodide (E.B.I.) therapy better results were obtained, but here again there were relapses in cases treated with this drug alone. Of Manson-Bahr's series of 134 cases thus treated 10 relapsed within 6 weeks, and 3 after as many as 9 separate 30-grain courses of E.B.I.—an indication of "emetine-fastness" on the part of *Entamœba histolytica*. Three cases were subsequently readmitted with liver abscess.

In 1925 a new drug called yatren was tried in this country. It consists of a close combination of iodine with oxyquinolin-sulphonic acid and 20 per cent. sodium bicarbonate, the iodine being so firmly combined that it is not split off by boiling, nor decomposed in the body. It can be administered in the form of pills or cachets, or by enema, the last being the method of choice when it is given in a 2½ per cent. solution. Between 1926 and 1931 no less than 181 patients were given combined E.B.I. and yatren treatment. The results of this combined method were such an advance on anything heretofore achieved that it will probably be many years before the method is superseded. Only two relapses were reported in this series, both of which yielded to a second course successfully.

Emetine per-iodide, a less nauseating drug, finds a place in the treatment of women and the more debilitated subjects, combined with yatren lavage. Stovarsol, so popular on the continent, is a doubtful specific but has a place in "after-treatment."

In conclusion, Manson-Bahr raises an important question in asking what criterion should be taken in assessing a definite cure. He is clearly right in believing that time alone can show, after testing various forms of treatment on a large number of *proven* cases. Active or cystic forms of *E. histolytica* were found in stools or sigmoidoscopic scrapings in all the cases he analyses.

AMŒBIASIS OF THE LIVER.

A second paper by Dr. Manson-Bahr and one by Mr. T. P. Kilner both deal with amœbiasis of the liver. Emphasising the extraordinary number and variety of signs and symptoms which may be manifested the former[2] recalls the dictum of Sir Patrick Manson that the diagnosis of liver abscess should always be carried at the back of one's mind. To quote figures, out of 45 cases only 3 showed any external bulging in the chest wall. In 40 cases the abscess was situated postero-superiorly in the right lobe—a fact which gave rise to discussion as to why that should be the site of election. In 45 per cent. of cases *E. histolytica* was found in the stools. The utility of radiography is emphasised, particularly in the demonstration on screening of elevation, fixation, or limited diaphragmatic movement on the affected side. "Doming" of the diaphragm was evident in one-third of the cases.

Manson-Bahr puts forward an interesting theory of the formation of liver abscess. He holds that it arises by the formation of necrotic foci in so-called hepatitis. Each focus consists of a "nest" of amœbæ, probably formed by fission of one original penetrating amœba, lying in the centre of each necrosing area. An early suppurative stage follows which may occur independently of active bowel infection. The necrotic tissue cytolised by the action of the amœbæ is sterile in a bacterial sense, and the amœbæ being still active are vulnerable to emetine in this stage, and the necrosis resolves without drainage. In the next stage the abscess cavity contains sterile pus and the lining walls active amœbæ, and therefore aspiration plus emetine therapy will do good. The final stage is one in which—possibly from lack of oxygen—the amœbæ are no longer active, the cavity is large, and secondary infection via the blood stream occurs. Open operation then becomes the only method of treatment, and later combined E.B.I. and yatren may be used to prevent reinfection from any uneradicated bowel infection.

Both writers describe the various measures of aspiration in detail, and Mr. Kilner[3] describes the technique of the open operation. He compares the uninfected amœbic abscess with the cold tuberculous abscess, and points out the similarity in treatment by aspiration in both conditions. Exploratory needling is the first step in surgical treatment, and the striking of pus also clinches the diagnosis. Once pus is found aspiration can be proceeded with and, if necessary, open operation performed.

For needling and aspiration local anæsthesia suffices as a rule, and causes no distress to the patient, even when as much as 1½ to 2 pints of pus are aspirated. Sometimes, however, pain is felt by the patient, and may be of two types. It may be either short, sharp, and due to needle pressure on a tightened liver capsule, or on the diaphragm, or persistent, cramp-like, and referred to the right shoulder. The latter type calls for general anæsthesia, and gas-and-oxygen apparatus should be kept close at hand.

Potain's aspirator is the best type to use when much pus requires aspiration, and with patience and care little blocking of the cannula by debris is found to occur. Where secondary infection is established the open operation with rib resection is essential.

These papers epitomise in plain language the most modern methods in treatment, both medical and surgical, of intestinal and hepatic amœbiasis. It remains for the medical profession in general to get these cases under treatment early. Fortunately it is beginning to be realised that amœbiasis may often be encountered in the temperate zone as well as in the tropics and subtropics,[4] and the condition is correspondingly less often overlooked.

"LOOSE MILK."

A COMMISSION of inquiry in New York City has apparently had no difficulty in deciding that loose milk—i.e., milk not sold in bottles or sealed receptacles—is a danger to health. A series of excellent photographs published in its report[1] illustrates the various ways in which contamination may take place. At the same time the arguments in favour of the retention of milk in this form are set out very fairly and at length. The main one is the low cost, and in a survey it was found that of poor families about half used loose milk and that half of all the milk they used was of this type, compared with less than a quarter for the entire market. The report includes the results of bacteriological examinations of loose milk and a comparison with those of bottled milk. The commission considered various devices for diminishing the dangers of loose milk but found none satisfactory. It comes as rather a surprise to learn that loose milk is still purveyed in more than 62,000 retail establishments in New York City; this includes 19,121 grocery stores, 16,958 restaurants, and 12,863 confectionery stores. In a particular month (February, 1927) the loose milk sold was about 47 per cent. of the total distribution of the metropolitan area. The commission recommends that the sale of loose or dipped milk not consumed on the premises be prohibited, and it advocates a general drastic reduction in the sale of loose milk.

A FRAUDULENT YOUNG PERSON.

To the Editor of THE LANCET.

SIR,—A paragraph appeared under the above heading in your issue of Feb. 27th, p. 494, which leads me to write to you. A begging-letter writer, signing as Jean M. Aldridge, is using my name as a means of approach to medical practitioners. I wish to say that she is entirely unknown to me, but I understand that she is quite well known to the Charity Organisation Society, who recommend that those who receive her appeals should communicate with the police.

I am, Sir, yours faithfully,
M. J. FENTON.

Stockwell-road, S.W., March 30th, 1932.

ALCOHOL IN FEVER HOSPITALS.

IN various publications in the last few years Dr. J. D. Rolleston has cast legitimate doubts upon the value of alcohol in treatment. He abandoned its therapeutic use over a quarter of a century ago and, after his appointment as medical superintendent of the Western Hospital, under the London County Council, he was able to persuade his colleagues also to cease to prescribe it. In this hospital nearly 2600 oz. of brandy were consumed in 1925; this figure fell after Dr. Rolleston's appointment (in 1926) to 25 oz. in 1927, 1 oz. in 1928, and none at all in 1929 and 1930. The effect of this experiment he measures in the case-mortality rates,[2] comparing those in the Western Hospital with those in all the fever hospitals under the Council; in the latter, although no statistics of the consumption are available, alcohol, it is stated, is still used freely, especially in the treatment of diphtheria, enteric fever, and in the bronchopneumonia of measles and whooping-cough. Throughout the four years, 1927 to 1930, the case-mortality from these diseases (and from scarlet fever) was, in nearly every case, lower in the Western Hospital. In 1927 and 1928, in neither of which years was alcohol used in the treatment of diphtheria, the case-mortality of this disease was the lowest in the nine acute fever hospitals of the Council. Dr. Rolleston's conclusion is that not only was the recovery-rate not lowered by the omission of alcohol from the treatment, but that convalescence was as rapidly attained as in cases treated in other hospitals by various alcoholic beverages. No statistical evidence is given on this latter point—the rapidity of convalescence—while, as the number of cases upon which the mortality-rates are based are also not given, it is not possible to apply any formal statistical test as to the significance of the differences in recovery-rates; but, as 18 out of the 20 case-mortality rates are lower in the Western Hospital, there is little doubt that, on the average, the experience without alcohol is favourable. On the other hand it may be suggested that the figures prove almost too much. For instance, the case-mortality rates (per 100) for measles and whooping-cough are as follows:—

		1927	*1928*	*1929*	*1930*
Western Hospital	Measles	5·5	5·7	6·5	6·2
All the Council's fever hospitals		6·7	7·2	7·2	6·6
Western Hospital	Whooping-cough	7·6	4·7	15·0	5·0
All the Council's fever hospitals		10·9	9·3	15·3	7·7

In every case, it will be observed, the rates in the Western Hospital are lower. If these differences are significant one of two conclusions must be drawn. Either alcohol is not only of no therapeutic value but is actually detrimental, so that its withdrawal results in a more favourable mortality-rate; or some other factor is favourably affecting the mortality in the Western Hospital compared with the other hospitals—e.g., the type of patient admitted—in which case the experiment is not clear-cut. Inclusion of the absolute numbers of cases involved would enable Dr. Rolleston's figures to be subjected to a more satisfactory critical examination, while further evidence seems essential that in the comparison between the Western Hospital and the other fever hospitals all factors likely to affect case mortality, except the treatment with alcohol, are equivalent. At present it is not clear that the presence or absence of alcohol in treatment is the only factor involved.

Appointments

City of London Maternity Hospital: WYNN-WILLIAMS, N. M.B., B.S. Lond., Assistant Resident Medical Officer CAIRNS, D. R., M.B., B.Ch. Belf., Senior Resident Medica Officer.

Queen Charlotte's Maternity Hospital: HECTOR, FRANCIS, M.D., Ch.B. Bristol, Senior Resident Medical Officer. STEPHEN, R. A., M.B., Ch.B. Aberd., Assistant Resident Medical Officer. CARLESS, Miss E. M., L.R.C.P. Lond., M.R.C.S., D.P.H., District Resident Medical Officer.

Certifying Surgeons under the Factory and Workshop Acts: ANDERSON, A. J. (P[illegible]an); HESKIN, R., M.B., Ch.B. N.U.I. [illegible]; and ROWLANDS, J. L., M.B., Ch.B. [illegible] Caernarvon).

Births, Marriages, and Deaths

BIRTHS.

BENTLIF.—On March 20th, the wife of P. Graeme Bentlif, M.A., M.B., B.Chir. Camb., of David-place, Jersey, of a son.

GARDINER-HILL.—On March 21st, at Wimpole-street, W., the wife of Dr. Harold Gardiner-Hill, of a son.

HUMPHERSON.—On March 24th, at Eccleston-street, Belgravia; the wife of V. W. Humpherson, L.D.S. R.C.S. Eng., of a son.

KENDALL.—On March 21st, at Buckingham-gate, the wife of A. Wallis Kendall, F.R.C.S., of a son.

LINDSAY.—On March 25th, at 47, Harefield-road, Brockley, the wife of Sidney S. Lindsay, M.B., B.S., D.O.M.S., of a son.

DEATHS.

HEBBLETHWAITE.—On March 18th, at Seven-arches, Lansdown-parade, Cheltenham, S. Montague Hebblethwaite, M.D., M.R.C.P.

PARKER.—On March 25th, at Rodney-street, Liverpool, Rushton Parker, M.B., B.S. Lond., F.R.C.S., Professor of Surgery, University of Liverpool, aged 84 years.

ROBERTSON.—On March 28th, Prof. George M. Robertson, M.D., F.R.C.P., F.R.C.S. Edin., aged 68.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

ADDRESSES AND ORIGINAL ARTICLES

THE RÔLE OF THE HÆMOLYTIC STREPTOCOCCI IN INFECTIVE DISEASE.

BY C. C. OKELL, *M.C.*, M.B. CAMB., M.R.C.P. LOND.,
PROFESSOR OF BACTERIOLOGY IN THE UNIVERSITY OF LONDON, AND BACTERIOLOGIST TO UNIVERSITY COLLEGE HOSPITAL, LONDON.

LECTURE I.

THE HÆMOLYTIC STREPTOCOCCI AND THEIR MODES OF ATTACK.*

THE literature relating to the streptococci is almost unbelievably extensive. The editors of the exhaustive catalogue of streptococcal literature published by the Pickett Thomson Laboratories estimate that their completed work will contain more than 10,000 references. In the present state of knowledge it would be idle to pretend that any satisfactory integration of this material can be achieved, but everyone who has to deal with streptococcal disease, in the laboratory and field, must needs have his own view of the unities and essentials which shall be his guide when faced with actual clinical and epidemiological problems. In these lectures it is my purpose to present one such personal view. The subject at least falls within the compass of the Founder's Suggestions, as it will be generally agreed that there are few subjects of greater epidemiological interest than streptococcal disease.

Classification.

At the outset of any discussion of the streptococcal problem we are met by the fundamental difficulty of having to conduct an argument the terms of which are ill-defined. Practical knowledge in the prevention and treatment of streptococcal disease must advance slowly while definition and classification remain in this present unsatisfactory state. This has been so generally recognised during recent years that possibly more attention has been paid to classification than to any other aspect of the subject. It seems then that this necessary preliminary to further discussion should be considered in some detail.

The streptococcus first named by Billroth in 1874 and given a definite generic position ten years later by Rosenbach is not more difficult to define than other genera of bacteria. On morphological grounds alone there is little difficulty in including or excluding a given example from the genus. The difficulty arises when we try to assign to the streptococci specific names of any importance, particularly those which carry a pathological implication. The bacteriologist here as elsewhere in so much of his work must steer a precarious course between the Scylla of pathological and the Charybdis of botanical classification, keeping a weather eye on either bow. A number of methods present themselves which may be used in dividing the streptococci into subgroups, such as fermentation reactions, agglutination tests, hæmolytic tests, tests for pathogenicity in animals or the believed potentialities of the streptococci as judged from their effects in natural disease. Each of these methods calls for some consideration.

CLASSIFICATION BY FERMENTATION REACTIONS.

The attempt to classify the streptococci by means of fermentation tests was first made on an intensive scale in 1903 by Mervyn Gordon,[1] who showed that by the use of a comparatively simple series of chemical substances the streptococci commonly met with could be classified into a number of groups. The materials used were milk, neutral-red, sucrose, lactose, raffinose, insulin, salicin, coniferin, and mannite. Some three years later Andrewes and Horder[2] making use of Gordon's methods published their Study of the Streptococci Pathogenic for Man. This paper constitutes an important landmark of streptococcal literature, and deals with other aspects than fermentation reactions, but at the moment I shall only refer to their views on *classification*. Unfortunately neither Gordon nor Andrewes and Horder gave more than passing attention to Schottmüller's division of the streptococci into hæmolytic and non-hæmolytic, but it is obvious that by their method, what we should now call the hæmolytic streptococci were divisible into two groups to which, after a thoughtful discussion of the dangers of bacteriological classification, Andrewes and Horder rather inconsistently gave the specific names, based essentially on fermentation reactions, of *Streptococcus pyogenes* and *Streptococcus anginosus*.

Although Andrewes and Gordon found their *S. pyogenes* commonly associated with suppurative conditions and their *S. anginosus* with inflammation of the throat including scarlet fever, the conclusion to be drawn from their work is that, though Gordon's tests provide a valuable and consistent method of study they fail to classify the streptococci satisfactorily in terms of pathogenic potentialities. For example, with regard to the scarlet fever question, they state that they "failed to indicate one variant as constant in or peculiar to the scarlet fever throat." Another who from the thoroughness of his work demands consideration is W. L. Holman.[3] His method was a simplified one combining Gordon's tests with Schottmüller's blood-agar plate method, the fermentable substances he eventually employed, being lactose, mannite, and salicin. By this method Holman divided the streptococci into eight hæmolytic and eight non-hæmolytic varieties. In this way the matter was carried to a stage which Andrewes and Horder would have undoubtedly reached had they given more weight to Schottmüller's classification. Holman's conclusion as to the pathological value of his method is summed up in the statement that "the streptococci are not specific in their disease production, at least so far as I have been able to determine." I have recently examined some 30 hæmolytic strains from diverse streptococcal diseases on a large range of the fermentable substances generally used in the laboratory. Another 71 strains were examined by Holman's simplified method, but in neither series could I find any grouping that could be linked with the clinical condition. With regard to scarlatinal strains the only statement that can be made is that they generally fail to ferment mannite.

The hæmolytic streptococci all appear to ferment the simple carbohydrates, but their powers of attacking the more complex reagents vary greatly even among strains from the same type of disease. Individual strains are remarkably consistent but by no means always so.

We may conclude then that fermentation tests are useful in identifying a particular individual strain of hæmolytic streptococci, but fail in supplying a method of classification of pathological importance.

CLASSIFICATION BY AGGLUTINATION.

Agglutination tests provide a very delicate method for differentiating bacteria but one which may easily transcend the requirements of both taxonomy and pathology. One need hardly mention that such well-defined bacterial species as the toxigenic bacilli of diphtheria and tetanus can be divided into consistent serological subgroups by these means. Yet it is admitted that these subgroups are of little practical importance. It has recently been realised that, for other reasons also, great caution must be employed in applying serological methods to bacterial classification. The work of Arkwright, Weil and Felix, and others on the peculiar features of bacterial variation has shown that most bacteria have a complex antigenic constitution, above all that they may exist in a "phase" for a number of generations when one antigen is dominant, eventually undergoing a *reversible* change to a phase in which another character takes the leading place. Thus agglutination methods at the present time have become a means of study of the variable rather than the consistent characters of bacterial species. Until the consistent antigens of a species are analysed and separated from those that are accidental and variable no serious application of antigenic criteria to the classification of bacteria can be attempted. In the cases of such fully studied groups as the salmonellas and the pneumococci we have perhaps reached the necessary degree of analysis but this certainty cannot be claimed for the streptococci. There is abundant reason to suppose that the antigenic structure of the hæmolytic group of streptococci is complex, and we have probably to recognise that they possess group and specific and possibly rough and smooth antigens. The work of Lancefield,[4] while it may eventually supply a method of attack, for the moment only makes the serological classification of the streptococci more precarious. This worker has done something to analyse the antigens present in the hæmolytic streptococci. She has separated three different bodies of immunological importance: (1) an antigenic nucleo-protein which is non-specific, overlapping with similar antigens from non-hæmolytic streptococci, pneumococci, and even the staphylococci; (2) a "type-specific" protein peculiar to the strain or to a certain number of strains and which she states is non-antigenic; (3) a "species-specific" carbohydrate apparently common to all hæmolytic streptococci and similar in general properties to the "hapten" of the pneumococcus, this being, of course, non-antigenic in the isolated state but able to act as a specific antigen when linked normally with bacterial protein. The quantitative redistribution of these antigenic factors in the history of an individual strain may obviously be a source of serological confusion.

---

* The first Milroy lecture for 1932, delivered before the Royal College of Physicians of London on Feb. 18th.

There is a good deal of evidence, though admittedly of an indirect nature, that suggests that the agglutinogenic constitution of bacteria may change during sojourn in the body, particularly if they are present without actively producing disease. Eagles [5] came to the conclusion that as cases of scarlet fever progress the streptococci from them become gradually and progressively less specific in their agglutination, so that in the end they can no longer be identified by these means. Gunn and Griffith's [6] observation that in 50 out of 100 scarlet fever cases a change of type took place during the course of the disease is explained by them as due to reinfection, but the alternative view might be taken that the individual strains had undergone a change of antigenic structure. It is possible too that the diphtheria bacillus undergoes a similar change of serological constitution in the throats of convalescents from diphtheria. The mechanism of such changes if they really take place is difficult to imagine, but Griffith's [7] amazing observation that one serological type of pneumococcus can acquire by contact the substance chemically and serologically characteristic of another type and moreover become permanently endowed with it, teaches us how little we yet understand of the principles underlying agglutination.

The technical methods used in much of the work done on agglutination makes little allowance for the complexity of the problem. They are arbitrar methods which are likely to emphasise certain ant genic properties at the expense of others and th give a distorted notion of the true state of affair Owing to the almost universal tendency of strept cocci to sediment rapidly when suspended in salin considerable difficulty has been met with in carryin out satisfactory agglutination tests with them. I the last decade these difficulties have been in a larg measure overcome and we are now in possession of body of results upon which some reliance can b placed. An array of workers, among whom a Gordon,[8] Bliss,[9] Havens,[10] Stevens and Dochez, and Griffith,[12] to name but a few, have shown th serological differences exist among the streptococ Nearly all these workers have focused on the proble of separating scarlet fever strains from hæmolyt strains of other origin. Opinions as to the success this attempt have varied greatly even among t workers themselves. The earlier view was th scarlatinal strains represented a stable and hom geneous subgroup, but this has been abandoned wi the advance of knowledge. In so far as there has bee any success in the identification of scarlatinal strai by agglutination it has been the outcome of t patient work of F. Griffith and his colleagues.

Griffith,[13] using a simple method which overcom most of the technical difficulties of streptococc agglutination, has succeeded in "typing" the stre tococci occurring in scarlet fever cases into four ma agglutination groups. Seventy per cent. of Griffith series of hæmolytic streptococci from scarlatinal cas were found to fall into these groups, leaving 30 per cen which form a miscellaneous group composed large of individualistic strains. The work has proved t more valuable because a number of other worke notably J. Smith,[14] G. R. James,[15] and Allison [16] ha accepted the same grouping while carrying out co current work, thus avoiding the confusion which often arises in independent investigations of th nature. In Griffith's series of 156 typeable scarlatin strains 6·4 per cent. fell into Type I., 36·5 into Type I 28·9 into Type III., and 28·2 into Type IV., and in more recent series of 600 cases examined by Allis 63·4 per cent. fell into one or other of Griffith's group 10·8 per cent. were Type I., 22·4 per cent. Type I 20·2 per cent. Type III., and 10 per cent. Type I Griffith formed the opinion that infections wi Types I. and II. tended to run a more severe cours and that Type II. infections were particularly ass ciated with complications, points not to be lost sig of in the epidemiology of the disease. Type II. w not at first found by Griffith except in connexion wi scarlet fever, but later it was found in cases of tonsi litis without rash and Allison found it in two cas where there was no history of the disease. Five cas of puerperal fever were reported by Griffith in whi the streptococci belonged to either Type I. or II In contrast to the high percentage of "typeable strains from scarlet fever cases, Allison, among 2 strains from streptococcal conditions other th scarlet fever, has recently found only 2 per cent. fall within Griffith's four types. The special intere of the work of Griffith and his colleagues is that shows that in this country at least there are serologic strains of hæmolytic streptococci which, from t point of view of scarlet fever, may be called *epidem* types. When they are met with they allow shrewdly to guess their source of origin and the potentiality as regards the production of scarlet feve The designation in this way of consistent types wi no doubt admit of the carrier problem being studie with greater precision. We are furnished with th ssier and marks of identification of the strains hich are most likely to give rise to mischief—at ast from the official public health standpoint. The sence of a strain from Griffith's four chief types ardly, however, amounts to a presumption of nocence in respect to scarlet fever, nor is its inclusion roof of its guilt.

McLachlan and Mackie,[17] though they took riffith's grouping as the basis of their work, found hat a minority of scarlatina streptococci were gglutinated by antisera for individual strains and hey observed no group agglutination. Absorption ests revealed the existence of agglutinogenic constituents common to the majority of hæmolytic streptococci isolated from various sources. I have also ound that absorption tests may be made to indicate a very general basic similarity among hæmolytic streptococci from different sources, particularly if heavy absorbing doses are used. McLachlan and Mackie expressed what seems to be the most reasonable view of the place of agglutination in relation to the general problem of classification when they said that "no serological distinction can be drawn between scarlatinal and other hæmolytic streptococci and a 'streptococcus scarlatinæ' group cannot be defined by serological methods." This view is not, as might appear at first sight, incompatible with that of Griffith.

The position is thus much the same as with the meningococci and pneumococci where in larger epidemics certain types tend to recur, yet in interepidemic periods the organisms may be serologically heterogeneous.

CLASSIFICATION BY HÆMOLYSIS.

Besredka[18] in 1901 and Marmorek[19] in 1902 pointed out that certain streptococci had the power of laking blood incorporated into the culture medium in which they were grown. There are two main methods for demonstrating this hæmolytic property of streptococci. The first was introduced by Schottmüller[20] in 1903. In this method a suitably distributed inoculum of streptococci is plated on nutrient agar into which is incorporated animal blood. It is not of great importance what animal is used as the source of blood. Sheep, horse, rabbit, and human blood have been used by different workers, and it is agreed that the capacity to hæmolyse the blood from these different sources is very similar though that from the horse and perhaps the rabbit seems to serve the purposes of the test better than others. It is, at times, not easy to draw a definite line between hæmolytic and non-hæmolytic streptococci grown on plates, and small variations in technique and in the constitution of the medium may produce divergent interpretations depending partly upon personal criteria. The detailed study of plate hæmolysis was undertaken by Theobald Smith and Brown[21] in 1915 and subsequently by Brown[22] himself in such detail that little further advance can be expected on this aspect of the streptococcal problem. The well-known method of classification used by these authors into α, β, and γ types has since been the basis of description of most of those who have studied the streptococci. In deference to practical necessities there has been a general tendency to simplify the classification into hæmolytic and non-hæmolytic forms, the former corresponding with the β-hæmolytic type or those which produce a clear zone of hæmolysis around their colonies, and the latter with those that do not fall clearly into the β-type. This method of division, though almost essential in everyday routine, evades in fact the most difficult issue of plate classification—the position of intermediate types.

The second method used in studying the hæmolytic power of streptococci avoids some though not all of these difficulties. This is the method of growing in fluid medium containing blood, which, like the plate test, was first seriously studied by Schottmüller. A convenient mode of carrying out this form of test which has been almost universally used in this country is that of M'Leod[23] who adds 0·5 c.cm. of a 5 per cent. suspension of red cells to a 15-hour culture in serum broth and examines for hæmolysis after an incubation of one and a half hours. There is no reason to doubt that hæmolysis indicated by solid or fluid medium is due to an identical property. The streptococci causing β-hæmolysis on plates give, in the great majority of cases, a positive M'Leod test, but whereas the interpretation of the peculiar appearances met with on plating often proves difficult, the result given by the M'Leod test is nearly always clear. In a recent series of comparisons carried out on 76 strains of "hæmolytic" streptococci, using rabbit blood for both tests, I only met with two strains in which a true contradiction occurred between the two tests, one M'Leod test positive and plate test negative and one the reverse. Four strains were doubtfully hæmolytic with both tests.

HÆMOLYSIS AND PATHOGENICITY.

Of all in-vitro properties bearing on pathogenicity, hæmolysis has attracted most interest. M'Leod,[24] who has perhaps given more attention to the study of this subject than any other modern worker, has summed up the position in the statement "that although the view that hæmolytic activity indicates virulence was unjustified, the opposite statement that there was no connexion between hæmolytic activity and virulence was as unsatisfactory."

There can be little dispute that the great majority of streptococci which cause serious human disease are hæmolytic. What then is the nature of the connexion between hæmolytic power and pathogenicity? The answer to this question, in the light of present knowledge, can only be tentative, but it is none the less worthy of consideration. But before it can be discussed some decision must be arrived at as to the nature of the methods of attack by which the streptococci produce disease.

The Offensive Weapons of the Hæmolytic Streptococci.

ERYTHROGENIC (RASH-PRODUCING) TOXIN.

In enumerating the offensive weapons of the hæmolytic streptococci I shall begin with the one perhaps now the best defined and understood—its exotoxin; as I intend to devote my next lecture entirely to this, I will rest content with a passing mention of it. I propose to call the toxin used in the Dick test and for active immunisation and responsible for the rash in scarlet fever the erythrogenic toxin of the hæmolytic streptococci. I have used this term because of the available adjectives "streptococcal" seems too general and "scarlatinal" too particular, while "Dick" toxin has legal limitations undesirable to accept for my present purpose. I may add that the erythrogenic toxin is neither hæmolytic nor pyogenic, nor is there any evidence that there is any direct connexion between the toxicity of streptococci and their pyogenic and invasive powers. The available evidence, which will be referred to later, suggests that the erythrogenic toxins of streptococci from the most diverse sources in human disease are immunologically identical.

PYOGENICITY.

The capacity for producing a pyogenic reaction may be taken as the lowest common denominator of the pathogenic activities of the hæmolytic streptococci and different as may be the *tout-ensemble* of the diseases they produce there is always to be found this element of pyogenicity. Robert Koch[25] in his great essay on Traumatic Infective Diseases, which inaugurated not only our modern knowledge of septic infection but much of our knowledge of bacteriology as well, describes the local "abscess" which occurs in rabbits when septic material is injected beneath their skin. "Such animals," he says, "have at first no symptoms of disease, a flat lentiform induration at the site of injection being all that is observed. After several days the induration extends in all directions but chiefly downwards and especially towards the abdomen and anterior extremities." If by the modern technique of intradermic injection hæmolytic streptococci are introduced, the series of events described by Koch takes place and there is little need to supplement his description except to add that in many if not in all cases a raised yellow purulent centre develops in the lesion. The histological changes are typical of all pyogenic inflammation even when visible pus is absent. For the purposes of a routine test I have injected 0·2 c.cm. of 16-hour broth cultures of several streptococci on the depilated skin of one rabbit. The reaction produced has been noted at the end of 24 and 48 hours. I have lately examined 71 strains of hæmolytic streptococci from different kinds of acute human disease, scarlet fever, erysipelas, septicæmia and various kinds of suppurations, and a few from apparently normal persons. Without exception all gave a reaction on the rabbit's skin, which I interpreted as pyogenic. Such a direct method of testing the pyogenic activity of bacteria seems to me at least as much value as any in-vitro criterion of "virulence" and is a more consistent test than intravenous injection.

Pyogenic activity is of course characteristic of many bacteria other than the hæmolytic streptococci, being also shown by the staphylococci, *Pseudomonas pyocynaca* and *Bacterium coli,* and it may be noted that these organisms are often hæmolytic as judged by growth on blood plates. The non-hæmolytic streptococci and pneumococci also often have the same power, though in a small series of these that I have examined rabbit reactions are produced with less certainty and seem in general to be less marked than in hæmolytic group. Though perhaps we cannot say that *all pyogenic streptococci are hæmolytic,* I think we are on safer ground in asserting that all hæmolytic streptococci are pyogenic. If, however, we could assume that the so-called non-hæmolytic streptococci which are pyogenic (including the pneumococci) were in reality endowed with an endocellular hæmolysin—the connexion between hæmolysin and pyogenicity might be brought still more close. Cole[26] has shown that active hæmolytic extracts can be obtained from the bodies of pneumococci by dissolving them in sodium cholate, or by allowing them to autolyse, or by freezing or by drying and grinding, and such may be true of the other non-hæmolytic streptococci that are also pyogenic.

It would certainly be a great simplification of our views on the pathogenicity of the streptococci if we could identify "hæmolysin" with the pyogenic property. A principle which has the characteristic power of hæmolysing the delicate red corpuscles might also, particularly if in suitable concentration, be considered likely to be able to damage or destroy other living cells particularly if in suitable concentr tion. There are a number of instances illustrati this, the hæmolytic toxin of Welch's bacillus al produces a local necrotic reaction in the skin a guinea-pig. An immune serum prepared again the red cells of an animal will produce local destructi of tissue when injected into that animal. Saponi which are hæmolytic in very weak dilution cau local necrosis of the skin when used in higher but st moderate concentrations, and the same holds f snake venoms. Perhaps the instance nearest to o present point is that of the newly studied toxin the staphylococcus. The pyogenic staphylococ also possess a hæmolytic property. Staphylococc *toxin, as Burnet[27] and others have shown, is* hæmolytic toxin in which hæmolytic power a toxicity as measured by the reaction produced in t skin of animals run parallel. This reaction too seer indistinguishable in essential pathology from t pyogenic reactions produced by the living staphyl coccus. R. T. Grant and I have recently carri out some experiments on the action of this tox on human beings. It is admittedly not easy produce pyogenic reactions by the introduction sterile materials into living tissue. Those substanc which appear most effective for the purpose a powerful protoplasmic poisons and coagulants su as the soluble salts of mercury and silver—su substances as produce and rapidly kill a small mass *cells while leaving the surrounding tissue* relative untouched and reactive. If the toxin of the staph lococcus is pricked into the human skin with a need as used by Thomas Lewis in his investigation on t injury reactions of the skin, a small pustule is produc similar in character to that produced by a stro *solution of silver nitrate introduced in the* same wa Here then we have a toxin which is both hæmoly and pyogenic though it would, of course, be prematu to claim that the living staphylococcus owes pyogenic properties entirely to this toxin. M'Le quite clearly recognises the streptococcal hæmoly as a toxic material, indeed he and Channon[28] use t term "thermo-labile toxin" for it. They ev suggest that this toxin in all probability is responsi for the invasive properties of the streptococci a they very properly draw attention to the ov emphasis that has been laid in recent years on t importance of the erythrogenic toxin in the gene problem of streptococcal pathogenicity. It shou have been abundantly clear by now that it pyogenicity and invasive capabilities that constitu the most dangerous and consistent weapons of t *streptococci, and that erythrogenic toxicity is on* a conspicuous though not in itself a very maligna feature in scarlet fever and in stray cases of oth forms of streptococcal disease.

If, however, we try to identify the hæmolysin wi the pyogenic principle of streptococci by direct expe ment we meet with difficulties which so far have n been overcome. This may in part be due to the fa that the streptococcal hæmolysin is one of the m labile of all immunological bodies and is extrem difficult to hold in high concentration sufficient long for the purposes of animal experiment. A final preparation of it has relatively low hæmoly activity and there is reason to suppose that duri the growth of streptococci much of it is destroyed rapidly as it is made. I have recently made ma efforts to demonstrate that the hæmolysin of strept cocci is also pyogenic, always up to now with a negati or at least equivocal result. What little is known the toxic properties of the streptococcal hæmolys has been obtained from a study of its action wh ntroduced intravenously into animals. Its effect nder these conditions is closely similar to that produced by the intravenous injection of any substance *ntravenously* into an animal the blood of which it s capable of lysing. If the dose is great rapid death ensues, presumably caused by intravascular hæmolysis, and if the dose is small and repeated, as M'Leod and McNee[29] have shown, anæmia gradually develops. These effects, however, give us no link with natural streptococcal disease unless it is with the signs of intravenous hæmolysis or of anæmia which are occasionally observed in certain severe and rare cases. The intravenous injection of animals with hæmolytic toxin of Welch's bacillus would give us equally little clue to the characteristic effects observed in ordinary gas gangrene which are easy to observe when the toxin is introduced locally into tissues in doses which do not cause a too rapid death of the animal.

If the search for a "pyogenic toxin" has been disappointing, that for a pyogenic antibody has proved equally so. We have tested the neutralising power of sera prepared in many different ways against the pyogenic effects of streptococci in the rabbit's skin. Serum of the ordinary antitoxic type, sera prepared using bacterial bodies, sera from man and animals recovered from acute streptococcal infection have equally failed to influence in a specific way pyogenic reactions in rabbits. A paper has just been published in which Todd[20] claims that he has been able to prepare neutralising serum against streptococcal hæmolysin. It will be interesting to see if the serum has any antipyogenic activity. It may be added, as germane to our general thesis, that Todd finds the hæmolysins of streptococci from diverse sources are antigenically the same.

There are many observations on record purporting to demonstrate that a local immunity exists to the pyogenic action of streptococci.

Cobbett and Melsome[21] state that the cutaneous lesions produced in the rabbit's ear by the injection of erysipelatous streptococci protect the parts directly affected against a subsequent inoculation, but their attempts to prove a general immunity are by no means convincing. Gay and Rhodes[22] obtained somewhat different results, finding that the skin of rabbits remained insusceptible to reinoculation of streptococci for three months or so, irrespective of the position of the original inoculation. In a still more recent study Amoss and Bliss,[23] like Cobbett and Melsome, found that the area previously inoculated acquired a partial resistance to subsequent infection while the rest of the skin remained fully susceptible.

Practically all the authors who have worked in this direction are agreed that any protection observed is temporary and some doubt its specificity. I am very doubtful how far such effects as these are due to specific forms of immunity and my own experiments on somewhat similar lines have never been able to convince me that a specific local immunity exists. The work of Cobbett and Melsome, of Gay and Rhodes, and of Amoss and Bliss as well as that of Birkhaug[24] was done with erysipelas strains and all these authors call the lesions they produced rabbit "erysipelas." This word is perhaps misleading, for some of the peculiar features of human erysipelas are only dimly reflected in the rabbit. Actually these reactions seem essentially the same as those originally described by Koch as following the introduction of septic material into the rabbit's skin and similar reactions may be produced by hæmolytic streptococci from practically any source including scarlet fever if they are introduced at a certain depth into the skin.

INVASIVENESS.

Invasiveness, the power rapidly to pass the local defences and infect the blood, is a property of the hæmolytic streptococci which in the present state of knowledge must be considered separately from pyogenicity, though it may well be closely connected with it. Characteristic though it be, this is perhaps the most variable of all properties of the streptococci, and we have good reason to suppose that it is not even constant in the individual strain. Most laboratory workers have found it a difficult and uncertain matter to exalt the lethality of streptococci by passage through animals. The facts of traumatic septicæmia in man suggest clearly enough that exaltation of lethalty may take place by passage through other human beings; but the exaltation seems of short duration and the streptococcus, so justly dreaded in the post-mortem room, appears to carry little danger in the laboratory where it is often manipulated still more intimately. Nor is virulence as tested by the power to cause fatal blood infection in animals any guide to invasive potentialities in man. The most virulent hæmolytic streptococcus for mice that I have examined killed in intravenous doses of 1/2.000.000 c.cm. Yet it was isolated from a trivial wound of the hand. With a strain isolated from a rapidly fatal case of infection contracted at autopsy, on the other hand, it proved very difficult to kill mice at all. The only experimental method which has been available for studying in the laboratory the invasive effects of streptococci has been by the study of the septicæmic effects of the organisms introduced intravenously, but though the end-result of streptococcal invasion is commonly septicæmia, invasive and septicæmic powers are not the same things and it is perhaps unfair to judge the defences against normal infection by the result of a surprise rear-guard attack. It is not however very easy to devise any other test which gives any information of value.

Anti-invasive immunity.—No subject in the immunology of the streptococci is more difficult than what is usually called "antibacterial" as distinct from antitoxic immunity. We might of course judge antibacterial immunity by a study of local pyogenic reactions, but I have already mentioned that so far only a negative answer has been obtained in this direction. The only available alternative method of study seems to be to determine if any method of immunisation can be devised which can protect such an animal as the mouse from the lethal effect of a parenteral injection of highly virulent streptococci. It is not always easy under these conditions to exclude the contribution of antitoxic immunity. Up to comparatively lately there has been some disagreement whether a specific "antibacterial" immunity to the streptococcus occurs. For example such experimenters as v. Lingelsheim[35] and Pasquale[36] stated they were unable to protect animals against invasion, while Killian,[37] Schloss and Foster,[38] among others, claimed to be more successful. Certainly nothing comparable to the clear-cut protective results of serum in the prevention of *pneumococcal* mouse infection has been recorded.

The work of Lancefield and Todd[39] has, however, done much to make the situation more clear. These workers have shown that under certain conditions effective immunisation can be obtained against the lethal effects of hæmolytic streptococci introduced intraperitoneally into mice.

They distinguish three kinds of colony variants as regularly occurring among all the hæmolytic streptococci they met with: (1) a matt virulent variety which contains a full complement of type specific protein; (2) a matt variant of attenuated virulence but still with its full complement of "type-specific" protein; and (3) a glossy *avirulent* variant which has lost most of its "type-specific" protein. In spite of the marked differences of virulence among these variants all had their full complement of specific carbohydrate and all produced erythrogenic toxin of similar potency. Yet passive protection of mice with serum prepared by immunising with killed bodies of the fully virulent or "matt attenuated" variants was obtained against the homologous strain of streptococcus, though not against hæmolytic streptococci in general. Sera prepared against the avirulent glossy variants did not prove protective. Experiments in which mice were actively immunised against the variants gave the same results.

It should be quite clearly understood that the protection depended not on the species-specific carbohydrate, but on the "type" specific protein, and that the "type" features of any individual strain are at most shared with only a few other strains. Thus nearly every streptococcus would call for an individual "antibacterial" prophylactic and therapeutic serum. It is perhaps possible that this opinion would have to be slightly modified if it were proved that Griffith's four agglutination types corresponded to Lancefield and Todd's type-specificity, but even if this were so it is difficult to envisage how it would affect practical serum therapy.

Some years ago Parish and I [40] noted the rather *remarkable effect of the ordinary antitoxin prepared* against the erythrogenic toxin of the hæmolytic streptococcus. If rabbits are injected intravenously with a virulent culture of the Dochez streptococcus they nearly always die, usually within two or three days. If, however, they have been previously injected with a sufficient dose of antitoxin they usually survive six days or more. Septicæmia is not prevented, for the streptococci can be grown from the blood of these animals with ease, but it is greatly modified in severity. The antitoxin-treated animals almost always developed subacute joint lesions and tended to die in a cachectic state at a later date. This form of protection was sufficiently consistent to form the basis of a test for antitoxin potency which has since been in extensive routine use. At the time we brought forward evidence which seemed strongly to suggest that the protection thus demonstrated was due to antitoxin itself and not to admixture with any other kind of antibody. We subsequently found that rabbits that die from early septicæmia may have a high level of toxin in their blood and it is not unreasonable to suppose that this is responsible for precipitating early death, at the same time explaining the effects of antitoxic serum. A similar explanation might be invoked for the success of prophylactic serum obtained by such earlier workers as Marmorek,[41] Bulloch,[42] Aronson,[43] and Besredka,[44] in rabbits and mice.

There is really nothing discordant between the observations of Lancefield and Todd and ourselves. The mechanism of the "antisepticæmic" effect of antitoxin is presumably quite different from that of the protective sera described by Lancefield and Todd, and though the action of antitoxin is not fundamental and specific, so far as it strikes at the invasive property of the streptococcus, it has the advantage of being practically applicable, whereas Lancefield and Todd's work clearly shows that "type" specific "antibacterial" sera are not.

It is reasonable then to suppose that no form of streptococcal antibody of prophylactic therapeutic activity of general application has ever been prepared against the hæmolytic streptococci except the antitoxin prepared against their erythrogenic toxin. This has a strictly limited use in therapeutics, and success in its administration will probably depend very much on how far the clinician can assess the contribution of erythrotoxæmia to the clinical features of his case.

Phagocytosis and counter-phagocytosis.—It has b customary in discussing the general defences agai pyogenic organisms to lay stress on the importanc cellular defences. It is in the background of m people's minds that pus represents the debris o fight of a somewhat personal nature between mi organism and leucocyte. I once heard an emin pathologist say a propos of this very argum "The Lord did not put leucocytes into the world nothing" and there seems little doubt that leu cytes and histiocytes must play some part in defence of the body against streptococci. W that part may be seems to me to be entir unexplained by any available knowledge thou the work of Gay [45] has done something to g definition to the problem. There is certainly ple of subject matter for the study of the place of c and tissues in resistance to infection, one of th being the apparent barrier action of granulat tissue on the extension of infection, an inquiry alre initiated by Gay and his colleagues, but there is immediate promise that such a study is likely contribute much to the practical prophylaxis a therapy of streptococcal disease.

Gay and Morrison [46] injected virulent streptococci i the pleural cavity of rabbits and observed the subsequ numerical increase of organisms in the exudate and extension of infection to the blood stream. If the pleu cavity was previously injected with materials as aleuronat strong egg white, both of which produce an exudate mai of polymorphonuclear cells, no significant protecti against streptococci resulted. If, on the other hand, m infusion or dilute egg white were previously injected exudate consisted mainly of histiocytes and the anim so prepared showed considerable resistance to the lo injection of streptococci.

It is, I think, equally impossible to define a specific mode of attack of the streptococci agai leucocytes. The term leucocidin has been devis to imply a substance obtained in filtrates from t streptococci which is supposed to have special toxic for leucocytes. Channon and M'Leod in their care work on the subject were unable to distingu hæmolysin from leucocidin, and more recently Al Evans,[47] though she recognises a leucocidal substan apart from hæmolysin, admits that the action of t substance is in itself small. Under these circu stances it appears to be safe for the moment to consid that if there is any marked action of streptococ filtrates on leucocytes it may be ascribed to the gene cytotoxic properties of the hæmolysin.

The Essential Unity of the Hæmolytic Streptococci.

I have attempted to give in crude outline what consider to be the more fundamental facts relati to the bacteriology of the hæmolytic streptococci a I would summarise them in the following way.

A large number of hæmolytic streptococci from t most diverse sources in human disease and al from apparently normal persons are essential similar having the same general morphological a biochemical properties. Agglutination tests, wh they show that serological differences exist amo members of the group, do not differentiate speci within the group.

There are three properties characteristic of t pathogenicity of the hæmolytic streptococci a these must be considered separately.

1. An erythrogenic (or rash producing) toxin, immunolo cally identical whatever the source from which the stra is derived. To this a neutralising serum is availab under the name of "scarlatinal antitoxin."
2. A pyogenic property, common to all hæmolytic strept cocci and perhaps closely related to streptococcal hæmolysi To this no antibody has so far been discovered.

3. An invasive property which may or may not be linked with the pyogenic property. To this also there is no general antibody available, though Lancefield and Todd's work suggests that antibodies to any particular strain could be prepared.

These three elements in the attack of the hæmolytic streptococcus, pyogenicity, toxigenicity, and invasiveness, vary in intensity from case to case. The strength of the host's defence against erythrotoxin and the site of the conflict also vary. These differences are sufficient to account for the varigated pathological and clinical patterns of human streptococcal disease.

If these views are accepted it must be admitted that the hæmolytic streptococci ordinarily met with in disease, in fact, constitute a species both on grounds of formal taxonomy and of pathology. With regard to the nomenclature of the species, Rosenbach's [48] term *S. pyogenes* has the unquestionable right of priority; hence it should replace Schottmüller's [20] term *S. hæmolyticus* which at present seems to have the greater vogue.

It would be quite unjustifiable to predict that other species of hæmolytic streptococci will not be established in the course of time. For example, the position of the so-called S. "epidemicus" and certain hæmolytic streptococci found in animals has not yet clearly been defined. The anaerobic hæmolytic streptococci have also to be given their proper position. But in the light of our present knowledge there is little doubt that it would save much confusion if bacteriologists would abstain from putting forward new species without good reason, and from what is almost worse—giving pseudo-specific names to what they would never themselves claim were species in any strict biological sense.

THE GALL-BLADDER AND CARDIAC PAIN.*

By CHARLES H. MILLER, C.B.E., M.D. CAMB., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO THE LONDON HOSPITAL.

To quote Osler [1]: "The diagnosis of pain is based on the patient's statement; the estimation of the severity is made by observation; the recognition of the cause demands thorough study."

The title of this communication presents a difficulty, for though it is customary and convenient to attribute a particular kind of pain to a particular organ, the anatomical labelling of pain has certain disadvantages in that it may lead us to take up a false position. Having noticed that on occasions disorders of a certain organ are associated with a particular set of painful symptoms, we may acquire the habit of constantly attributing these symptoms to disorder of the organ with which we have previously found them associated.

On these grounds the term "cardiac pain" is open to criticism, but it is difficult to find a better. It is one of those dangerous terms which is dismissed by saying "everyone knows what you mean." "Sternal pain" has a good deal to recommend it, but the objection is that pain of cardiac origin is not always sternal. Also it is desired to include angina pectoris under the heading. Here again are difficulties. Various forms of angina pectoris are described in the text-books. The term "true angina pectoris" is often used, but it is of the same quality as the term "true epilepsy," and may be a convenient cloak for what is not well understood.

Parkinson,[2] in a communication on sternal pain, has said that "sternal pain is not synonymous with angina pectoris, but it can be held to include most of the cases so called. The diagnosis may be completed by deciding what pathological lesion is the cause of the pain. If the use of the term 'sternal' or 'cardiac' pain were more general even at the expense of the term 'angina pectoris' it would result in an earlier, more frequent, and more certain diagnosis of cardio-aortic disease."

Angina pectoris is defined by Douglas Powell [3] as a "sudden paroxysmal disturbance of the heart's function accompanied by severe pain, distressed breathing, and a vague and instant apprehension of death." Allchin [4] describes it as "acute distress in the chest which consists of at least three elements—pain, faintness, and a sense of dying."

On the whole there are fewest objections to the term cardiac pain. The situation of the pain may be sternal, but there may be no pain in the chest. In one of my cases of cardiac infarction there was agonising pain which the patient localised in his left humerus. The pain commonly comes on with effort, but in cardiac infarction the patient is often in bed.

---

* Based on a communication made to the Association of Physicians of Great Britain and Ireland.

The pain may be slight and dismissed as trifling indigestion, or it may be so severe that the patient is collapsed and may even die during the attack. The term used must be as wide as possible in its meaning. The production of such pain is dependent on many and various factors. With a perfect coronary circulation and a perfect myocardium, there would not be an expectation of pain. There may be organic myocardial change due to syphilitic or other infection, or to degeneration of the coronary arteries. The coronary circulation may be imperfect either from the quality or the quantity of the blood that is circulated. But damage to the myocardium or coronary vessels does not necessarily mean pain. Several factors contribute to the symptoms. Cold air, annoyance, a hastily swallowed meal may be the exciting cause. But sometimes they fail to produce the pain that has occurred on other similar occasions. Further, a certain sensitiveness of the patient has to be considered, and in such circumstances the use of bromides may be regarded as one of the blessings of medicine.

It is a matter of common experience for the cardiac condition of the patient to be improved after the removal of a septic focus such as a dead tooth or a chronic appendix. The general health is improved after the operation, and if cardiac symptoms have been prominent they may become less pronounced or disappear. Several cases of serious disturbance of rhythm have in my experience and that of others been greatly improved after operation on the gall-bladder.

DISORDERS OF THE GALL-BLADDER.

With disorders of the gall-bladder we have several factors that are of special importance that may associate their symptoms with those of the heart. The gall-bladder may be a focus of chronic sepsis; further, it may contain stones, the passage of which is associated with severe pain. There may be some disorder of chemistry which causes widespread defects of circulation. There is the pain of gall-stone colic, one of the most severe of all pains. The heart and the gall-bladder are each capable of producing devastating and demoralising pain. Their innervation is from neighbouring regions of the central nervous system. It would be surprising if the symptoms were always so clear-cut that they could be given their true significance. Many practitioners have had cases which have perplexed them as to whether they were dealing with a cardiac or a gall-bladder disorder.

My own interest in the possible association began many years ago. A doctor came in haste to the hospital to take me to the bedside of an elderly Jewess whom he had been treating for angina pectoris. He said that she was in a bad attack and was dying. The patient was stout, pale, sweating, with a feeble pulse. She was in great pain, and pointed to the left side of the sternum, moving her hand about, and on questioning said she had pain in her arms. A large dose of morphia was given and a bad prognosis. Two months later I was asked by the doctor to admit the same patient to hospital as she was jaundiced and had a large gall-bladder. The gall-bladder was emptied of stones and drained. The attacks of pain ceased. Obviously I considered that I had made a mistake in diagnosis and determined not to be misled again.

Turning once more to the task of discussing cardiac pain, it can be said that the term "cardiac" can be applied to pain, in the origin of which the heart is directly or indirectly concerned, and that it is often impossible to say whether the connexion of the pain with the heart is direct or indirect. There is much to be discovered about cardiac pain. We have in the past been much impressed by the discovery of segmental areas of hyperæsthesia after an attack of cardiac pain but the phenomenon has still much that is obscure in its occurrence.

For instance, a man who had an attack of cardiac infarction was left with the liability to sternal pain on occasions. Usually the pain would come on when he was walking, especially on a cold day or soon after a meal. But after the pain had come on one of two things would happen. Either he would have to stand still until the pain had gone, or he could continue walking and the pain would go. He could never tell at the onset of the pain which he would have to do. The same patient, after having the sternal pain of effort, would have a local erythema of the skin over the area where the pain was felt, a curious phenomenon for which an explanation is lacking.

It cannot be said that there is any one feature of cardiac pain that is constant. Its situation is varied; its severity is of differing degrees; it may render the patient immobile, or he may be restless and even walk about as sometimes happens in cardiac infarction; it may last a few minutes or many hours. The sense of dying is not solely significant of angina pectoris, as the following case shows.

I am indebted to Mr. Robert Milne for the following notes.

A married woman, aged 56, was wakened by severe pain down the left side, arm, and trunk. It was followed by epigastric pain, nausea, flatulence, and diarrhœa. The pain lasted 5–10 minutes. There was the impression of impending death. Arteries, blood pressure, pulse, electrocardiogram were normal. An inflamed gall-bladder was drained and a solitary stone removed. Four years later she reports that she has had no return of pain and is in much better health. Here was the pain in the left arm and the sense of impending death.

Again, a medical man, who had reason to suspect his gall-bladder, was hurrying after a meal when he was seized with a bad attack of angina pectoris. According to his account it was an attack that could not be called by any other name. After the removal of his gall-bladder there has been no return of such symptoms, and he can more than hold his own with men of his age.

The following notes concern a medical man who was engaged in a busy practice.

At the age of 48 he had his gall-bladder emptied of stones and drained. The operation was followed by ten years of comfort. At the age of 58 there was recurrence of niggling pains and flatulence; there was also breathlessness and palpitation. At the age of 59 he was urged by a heart specialist to give up practice on account of "myocarditis," and he did so. At the age of 65 he had pneumonia and was very ill. At the age of 68 he first consulted me. He complained of anginal attacks. He had been seen by his doctor in two. He had lost consciousness in them. He could not go upstairs without pain. He could walk a little, but only on the flat on account of sternal pain. He also had bad attacks of colicky pain in the gall-bladder region with pain going into the right shoulder. In his own opinion he was having cardiac as well as gall-bladder symptoms. The skin was over-sensitive to pin over the right shoulder and the ulnar borders of both arms down to the little fingers. The pulse-rate was 76 per minute, and regular; the blood pressure was 138 systolic and 94 diastolic, and the examination of the heart revealed nothing abnormal.

I advised him to see a surgeon and approved cholecystectomy. The surgeon declined to operate unless he had the approval of a cardiologist. The cardiologist examined him; the electrocardiogram was pronounced to be within the bounds of normal, but on account of the general condition and his post-pneumonic lung the cardiologist advised against operation. The surgeon was approached once more and consented to operate, which he did, and with great skill and success removed the gall-bladder. Now, four years later, the patient is able to walk with comfort and the cardiac pain has gone. He still has some dyspepsia which is kept under control by medical measures.

There are several points about this case. At the age of 59 the heart was under suspicion. He has since gone through pneumonia and a severe abdominal operation. He himself as well as his medical advisers considered that he had cardiac as well as gall-bladder pain. The removal of the gall-bladder has removed his cardiac pain and a great deal of his physical infirmity. He has left only the symptoms of flatulence. Instead of being a haggard, miserable individual barely enduring an almost intolerable existence, he is bright, happy, and moderately active.

These cases illustrate the connexion between the symptoms which resemble those of a cardiac disorder and a pathological state of the gall-bladder.

A REVIEW OF THE LITERATURE.

The literature on the subject is copious, especially on the other side of the Atlantic. Brockbank[5] has pointed out that cholelithiasis is more common in patients who suffer from chronic heart disease. Mills[6] also, in reviewing the cases at St. George's Hospital, came to a similar conclusion, and Schroeder is quoted as having found the same condition. But this is not the condition with which I am here concerned.

Dr. de Havilland Hall[7] at the Medical Society of London described the case of a man between 50 and 60 years who suffered from excruciating pain in the region of the heart with much depression and faintness. Nitrites did not relieve but blue pill and mist. alba were beneficial. The condition was diagnosed as angina pectoris by himself and another physician. The pain continued for three to four months. Later there was an attack of gall-stone colic followed by a hepatico-bronchial fistula. The angina pectoris ceased.

Sir R. Douglas Powell[3] described one case in which hepatic colic was complicated with a fatal attack of angina pectoris, which it apparently excited; and another case of distinct hepatic colic with the passing of biliary grit, and at other times cardiac pain of an anginal kind with faintness and oppression.

Sir James Mackenzie[8] called attention to the fact that John Hunter was found to have gall-stones as well as degenerate coronary arteries; and has expressed his opinion that Hunter's earlier symptoms were biliary and not cardiac. He also described a case of angina pectoris which was improved by diet and cured by cholecystectomy.

In his remarks about biliary colic Osler[1] says: "Palpitation and distress about the heart may be present, and occasionally a mitral murmur occurs during the paroxysm, but the cardiac conditions described as coming on acutely in biliary colic are due to persistent myocardial degeneration not infrequent in patients with gall-stones."

Rolleston[9] has written that "the absorption of toxin from inflamed gall-bladder may cause myocarditis, angina attacks, and cardiac failure," and "angina and anginoid symptoms in patients with gall-bladder disease may be due to the exhaustion of a poisoned myocardium," and "the pain of biliary colic sometimes resembles angina."

The possible connexion between cardiac and biliary disorders has not escaped the notice of surgeons. Moynihan has used the phrase "cholecystitic heart." He refers to the irritability of the heart in such patients. Fint[10] attributes the irritability to the increase of circulating bile-salts.

It has happened to many physicians to decide that acute symptoms of the upper abdomen were due to cardiac infarction, and to stay the hand of the surgeon. In these cases acute disorder of the gall-bladder may be simulated. In America the subject has produced extensive literature. C. B. Leech[11] examined 116 proven cases of gall-bladder disease, exclusive of malignancy, before and after operation. His general conclusions were that there is no definite relationship between gall-bladder disease and disease of the cardiovascular system, and that the risk of operating on patients with gall-bladder disease and organic cardiac disorders was no greater than for other similar operations. On the other hand, R. H. Babcock[12] regards chronic cholecystitis as a cause of myocardial incompetence, and reports that improvement in the cardiac condition has followed operation.

S. A. Roberts,[13] writing on the diagnostic relations between the gall-bladder and the heart, concludes that (1) the patient with a diseased gall-bladder previous to any symptoms characteristic of cholecystitis with or without a cholelithiasis, may present symptoms of early heart failure or angina pectoris, or both; (2) in middle and old age heart failure or angina pectoris may be produced or accentuated by a diseased gall-bladder; (3) in both conditions the gall-bladder may be the cause, but all the signs and symptoms may appear cardiovascular in nature; (4) it is suggested that cholecystography may help to differentiate; (5) such patients should not be deprived of the benefits of surgery.

Graham,[14] quoted by Roberts, has written: "We have observed brilliant results in cases of heart disease followed by cholecystectomy after it had been determined that there was a pathological gall-bladder." Many others, including Lichty,[15] Willius and Brown,[16] have written and expressed similar views.

More recently Schwartz and Herman[17] have contributed a study of 109 cases of gall-bladder disease. Their investigation shows that 63·3 per cent. of cases had associated myocardial disease, and that the majority were obese; an infected gall-bladder and obesity are equally responsible for the myocardial damage of patients with chronic cholecystitis. Severe and mild cholecystitis, judged by clinical standards, have the same effect on the heart. Burns[18] in Canada also has called attention to the frequency with which cardiac symptoms simulate abdominal conditions.

It is clear that on the continent of North America the subject has attracted the attention of many observers, and that among those quoted, with one exception, the opinion is that there is some connexion between cardiovascular disorder and non-malignant disease of the gall-bladder.

CLINICAL ASPECTS.

Reference has already been made to four patients, two of whom were doctors, whose symptoms were those of angina. In all of them operation has been followed by relief of cardiac symptoms. Many other cases could be quoted from my own records, and still more from the records of other observers.

The difficulties of distinguishing between the symptoms of cardiac infarction and those of an acute gall-bladder have been mentioned, but the difficulty is increased by the fact that the same patient may be afflicted with both conditions. I am indebted to Dr. J. Parkinson and Dr. J. Fawcett for the notes of the following case.

Mr. A, in 1925, at the age of 61, had an attack in the night of mid-sternal pain which extended down both arms. One month later he was found to have a blood pressure of 170/100; the arteries were thickened and the aorta somewhat prominent on radioscopy. Wassermann reaction was negative. The electrocardiogram was deeply inverted in lead I., and during the next few months this became less pronounced. In 1927 he had some abdominal pain and tenderness for six months. In December, 1930, he had a severe attack of gnawing, sickening pain which took five minutes to reach its height and gradually became easier. A week later the pain returned, with vomiting. There was great abdominal tenderness in right costal margin and epigastrium. The next day there was a trace of bile in the urine as well as some albumin and sugar.

The diagnosis was made of gall-stones, cholecystitis, and pancreatitis. He declined operation at the time. He had several minor attacks, and a worse one in February, 1931. Four days later Mr. R. P. Rowlands operated. The conditions diagnosed were found, and fat necroses were present. He made a good recovery, and four months later reported that he was much better in all ways.

Dr. J. A. Ryle has kindly furnished me the following notes of four of his cases.

Mr. B, aged 58, a hard-working business man who had lived well and smoked heavily had for three years complained of retrosternal pain on cycling and walking fast. After being retired from his firm he began to have frequent anginal attacks, some of which lasted an hour. They were relieved by heroin but not by amyl nitrite. The pain was "gripping," and felt over the sternum and præcordium, and down the left arm. There was neither pyrexia nor pulse disturbance. Earlier in the year the blood pressure had been 190 systolic. Before the recent attacks it had been 160, and now it was 130. There was a trace of albumin in the urine. A coronary occlusion was suspected, and prolonged rest advised. Two days later he had a stomach-ache and was sick. The next day he was distended, and the day after he was operated on for an empyema of the gall-bladder by Mr. Cecil Rowntree. The latest report is that he has had uninterrupted good health since convalescence, and he is no more "puffy" than would be expected in a man who is badly out of training.

Mr. C, aged 67, had been treated satisfactorily for obesity, glycosuria, and myocardial symptoms. On Jan. 1st, 1931, he had an attack of severe epigastric pain and sickness, followed by pyrexia and rigidity of the right upper quadrant. No definite jaundice. There was a leucocyte count of 18,750. Acute cholecystitis was diagnosed, and as the symptoms were abating and the patient was not a good subject, operation was not advised. Four days later he was seized with severe anginal pain radiating down the left arm, which lasted a long time. The attack left him exhausted and frightened. The pulse remained slow and regular 60 to the minute. No pericardial friction, BP 105/90, a slight rise in temperature. Coronary thrombosis was suspected. During the next 12 months he had several attacks, and one was accompanied by anginal symptoms. Another was very severe, and was followed by rather intense jaundice but no anginal symptoms. Since then he has been wonderfully well.

Mr. D, aged 69, had had an attack of abdominal pain with jaundice seven years before. Two years later he began to have anginal attacks, the pain being to the right of the sternum and radiating into the right side of the neck and jaw. The blood pressure was 170/120. From this time he could not walk faster than two miles an hour without inducing pain. He had two attacks of biliary colic with pyrexia, a palpable gall-bladder, and a leucocyte count of 12,300. The gall-bladder did not fill with the dye and the electrocardiogram was normal. A large thickened gall-bladder containing stones was removed. Six days later he had a typical attack of coronary thrombosis with sternal pain radiating to the left side of jaw, neck, and shoulder. There was slight pyrexia, pericardial friction, and three days later a small pulmonary infarct. He made a satisfactory but slow recovery but has remained incapable of effort.

Miss E, aged 46, a hard-working energetic woman, had in 1927 a typical attack of coronary thrombosis with pain referred to the left suprascapular region, with a pulse of 120 and a temperature of 100·4°, and the next day a pericardial friction. Later the electrocardiogram confirmed. At this time and frequently since there has been tenderness in the gall-bladder region, and occasionally there has been spontaneous pain there. She has frequently been better after courses of urotropine. The blood pressure has never been raised, and there is no evidence of arterio-sclerosis.

The following notes are those of a patient whom I saw recently with Dr. A. Clark-Kennedy and Dr. D. Henning Belfrage.

Miss B. K., aged 64, was seen by Dr. Belfrage in a typical attack of angina; later she was jaundiced. Recently she has had pain in the chest and throat chiefly on walking. She was now able to walk only a few yards and very slowly. She has also had several attacks resembling gall-stone colic. She had been radiographed by Dr. Cecil Bull, and the gall-bladder was shown to be thickened and containing stones. An electrocardiogram had been done which showed a left-sided preponderance and inversion of T-wave in lead II. She was operated on by Mr. Claude Frankau, who removed a thickened gall-bladder containing stones. Two months after the operation she is reported to be in excellent health and able to walk uphill and upstairs without pain, and is very busy getting into a new house and moving furniture about.

These cases illustrate sufficiently well that it is possible for the two conditions to occur in the same subject. It is also significant that in these cases and in those quoted earlier the gall-bladder may be closely concerned with the production of cardiac pain.

It has to be remembered that the two conditions occur at the same time of life; that the indigestion of the gall-bladder patient has flatulence for its most constant symptom; that gastric flatulence is a serious trouble to the cardiac patient; and that cardiac symptoms are commonly relieved by the eructation of gastric flatus, and that the treatment of cardiac patients is often dietetic with the object of reducing weight and flatulence. On the other hand, cardiovascular disorders are said to be commoner in males, and gall-stones and cholecystitis in females. But women suffer considerably from cardiac defects and symptoms. Their cardiac pain is called "pseudo-angina," and "wind round the heart" if it is not severe. But women also suffer from cardiovascular degeneration, and they suffer to a greater degree than men from cardiac adiposity. It would appear then that disorders of the two organs may be present in the same individual, and that the symptoms can be confused.

MORBID ANATOMY.

Through the kindness of Prof. H. M. Turnbull I have had the opportunity of examining the mortem records of the London Hospital for ten y In all 350 cases of non-malignant disease of the bladder—i.e., cholecystitis and/or gall-stones—discovered, 202 females and 148 males.

The details of the condition of the arteries myocardium were noted and compared with t of patients of the same age-groups whose bladders were normal (Table I.). A comparison possible, as the descriptive terms employed by W. W. Woods and Dr. A. B. Bratton are stri used. Only certain words are employed, sli moderate, considerable, severe, and very sev Though two cases described in the same terms not have been exactly identical, the variation so slight that it could be disregarded. Over a thous cases were taken for comparison, and as nearly possible three were taken to compare with each g bladder subject in the different age-groups. But

TABLE I.—*Comparison of Degrees of Atherom Marking.*

Age.	Males.				Females.			
	G.-B. cases.		Non-G.-B. cases.		G.-B. cases.		Non-G. case	
	No.	Av.	No.	Av.	No.	Av.	No.	
21–30	None		None		4	2·00	26	2
31–40	7	4·57	48	2·87	3	2·66	48	2
41–50	14	4·28	133	4·37	38	4·36	108	3
51–60	55	6·14	176	4·65	69	5·79	214	4
61–70	47	7·70	133	4·99	60	6·50	110	5
71 and over.	25	7·68	60	7·70	28	7·85	31	7
Total	148		550		202		537	

G.-B. = gall-bladder.

The method of marking was to give 2 marks for "slight."
" " " 4 " " "moderate
" " " 6 " " "considera
" " " 8 " " "severe."
" " " 10 " " "very seve

The above table is shown for interest. It is not meant to statistical value.

system of recording morbid processes is capable of exact measurement, and no claim is made here that it is. On the other hand, care has been taken to put a correct value on terms that have been as far as possible used with uniform exactness. The first comparison was made of those cases in which the degree of atheroma was described as "severe" or "very severe" (Table II.). It will be seen that in both males and females the differences in the two groups for the age of 71 years and upwards are not significant, there being little difference. Below this age there are differences to be noted. Among males between the ages of 41 and 70 there are many more cases of severe atheroma among the gall-bladder cases than among non-gall-bladder cases. Among females the difference is not so great, but still a definite majority.

TABLE II.—*Severe and Very Severe Atheroma.*

Age.	G.-B. cases.	Non-G.-B. cases.
	MALES.	
21–40	No cases.	No cases.
41–50	3 out of 14 = 21·4 %	7 out of 133 = 5·2 %
51–60	22 out of 54 = 40·7 %	14 out of 176 = 8·0 %
61–70	29 out of 49 = 59·1 %	24 out of 142 = 16·9 %
71 and over ..	13 out of 19 = 68·4 %	30 out of 53 = 56·1 %
	FEMALES.	
21–40	No cases.	No cases.
41–50	3 out of 38 = 7·8 %	3 out of 108 = 2·7 %
51–60	14 out of 69 = 20·2 %	17 out of 214 = 7·9 %
61–70	25 out of 60 = 41·6 %	28 out of 110 = 25·5 %
71 and over ..	18 out of 28 = 64·2 %	17 out of 23 = 73·9 %

The figures were submitted to Prof. Major Greenwood, F.R.S., who very kindly examined them and reported as follows:—

> "We have gone into the statistics of these data, taking the two tables where the classification is 'severe' and 'very severe' as our basis, and have asked ourselves whether the differences are statistically significant. In plain English, are the odds against the excess percentage of atheroma in the gall-bladder group being a mere freak of chance so great that it is unreasonable to think that chance is the explanation? With regard to the age-groups 51–60 and 61–70, the answer is that for both males and females the difference is far greater than any which can reasonably be attributed to play of chance. In the age-group 41–60 for females, the difference is not so large that a chance variation can be ruled out; in the age-group 41–50 for males, however, the difference is too great to be reasonably explained by chance. In the age-group 71 and onwards, the differences both for males and females are not significant. When the two distributions are considered as wholes, neither of them is consistent with a mere chance difference. It seems to me, therefore, clear that it is established on this sample that the frequency of severe atheroma as defined is greater in the gall-bladder cases."

Other comparisons were made. An attempt was made to give a numerical value to the different degrees of atheroma. It is not claimed that such a method is satisfactory, nor is it strictly applicable to morbid processes. At the same time it is interesting to note that in the gall-bladder cases the degree of atheroma is greater than in the others. Also that in the age-group 71 and upwards in both males and females the figures tend to approximate, and that the difference at other ages is greater in males than in females. Coronary thrombosis was apparently commoner in the gall-bladder cases, especially in males between 51 and 70. Thus in 102 male gall-bladder cases between 51 and 70 there were eight cases of recent cardiac infarction, whereas in the non-gall-bladder group there were three cases out of 133. Also in these 102 gall-bladder cases areas of myocardial fibrosis were noted in 13. These figures are interesting, though they are obviously of no statistical value. Among females the total figures for coronary thrombosis are still smaller, but even so the gall-bladder cases have a majority.

Without claiming too much, it can be accepted that among patients who have diseases of the gall-bladder of a non-malignant nature, the frequency of severe arterial degeneration is greater than in those who are free from gall-bladder disease, and that the degree of arterial degeneration can be expected to be higher among gall-bladder cases.

COMMENT.

An attempt has been made to discover any factor which might have a bearing on the relation of the gall-bladder to cardiac pain. Clinically, symptoms attributed to disorders of both organs are not uncommonly found in the same patient; also several patients of my own and other observers have been relieved from cardiac pain after operation on the gall-bladder. Is it possible for a diseased gall-bladder to produce symptoms that would be agreed to be cardiac? This question cannot be answered dogmatically, but it is possible that disease of the gall-bladder can produce the same shock and symptoms similar in type, localisation, and severity as disease of the heart. But if cardiovascular degeneration in gall-bladder disease is in advance of its years, it is possible for the heart to add its particular symptoms to those that afflict the patient. It may be that the presence of a diseased gall-bladder is in itself sufficient to cause a middle-aged heart to produce unpleasant cardiac symptoms. Cases occur in which the symptoms are cardiac, and later a gall-bladder attack supervenes which calls for operation. After the operation the cardiac symptoms disappear. We cannot be certain, we can only speculate about such cases. But it can be said that if in a patient with cardiac pain there is any justification for condemning the gall-bladder, surgical treatment should be advised. Many patients are refused operation on account of the cardiac symptoms. I believe this attitude is wrong. The operation is a severe one, but in my limited experience the results have been good, and in some cases remarkable. In America Leech found that the risk of a gall-bladder operation was no greater than for other operations in patients of the same age. Roberts also is definite in his statement that "such patients should not be deprived of the benefit of surgery." In my own experience I have seen no reason to regard the risk as being great enough to forbid operation.

SUMMARY.

1. Clinically there may be considerable resemblance between the severe pain of the gall-bladder and cardiac pain, and there may be overlapping of symptoms in severe attacks affecting either organ. 2. Both types of pain can occur in the same subject and be recognisable as distinct. 3. Disorders of both organs may be present in the same patient. 4. Cases have been quoted in which surgical treatment of the gall-bladder has been followed by relief from both types of pain. 5. If there is any reason to suspect the gall-bladder in any patient who has cardiac pain a full investigation of the gall-bladder should be made, and if sufficient evidence is found, operation should be advised. 6. A study of morbid anatomy reveals the fact that in subjects with diseased gall-bladder the degree of arterial degeneration was higher and the cases of severe arterial degeneration were more numerous than in those whose gall-bladders were healthy. 7. That being so, it would appear to be rational to deal thoroughly with cases of cholecystitis or gall-stones as soon as diagnosed.

I desire to express my gratitude for allowing me to use their clinical notes to those physicians and surgeons whom

I have already mentioned. For allowing me to examine the records of the London Hospital Pathological Institute I am deeply indebted to Prof. H. M. Turnbull and to Dr. A. B. Bratton, and Dr. W. W. Woods for their help in the investigation. I wish to express my thanks also to Prof. Major Greenwood for his kindness in examining the figures *and in giving the opinion which I have quoted.*

INTRAVASCULAR OCCLUSION OF THE MESENTERIC VESSELS.

BY FRANK D'ABREU, M.B. BIRM.,
RESIDENT SURGICAL OFFICER, QUEEN'S HOSPITAL, BIRMINGHAM.

INTRAVASCULAR occlusion of the mesenteric vessels is a catastrophe which is attended by an extremely high mortality-rate but is apparently not so rare as was formerly supposed, and should always be kept in mind in an acute case showing signs of intestinal obstruction. Five cases have occurred at the Queen's Hospital, Birmingham, during the last seven years, and I was permitted by the surgeon in charge to operate upon Cases 4 and 5. This short series illustrates certain points about the symptoms which seem to be adequately explained by consideration of the pathology.

Briefly, mesenteric vascular occlusion may be classified in the following way (Larson [1]): (*a*) arterial; (*b*) venous; (*c*) mixed arterial and venous—this variety is secondary to strangulation and will not be further considered.

(*a*) The *arterial cases* may be due either to an embolus, when the causative factor—a cardiac mural thrombus or valvular vegetation—is present, or to thrombosis of the vessel, when arterio-sclerosis or a generalised arteritis from sepsis is found. In this division may be included a group of cases which are labelled "intermittent mesenteric claudication" by Larson. This is a group which gives rise to much speculation. From time to time surgeons are confronted with puzzling cases where the signs and symptoms of subacute intestinal obstruction are present but on laparotomy nothing obvious is found and recovery takes place. Klein [2] quotes nine cases which he diagnosed as early mesenteric thrombosis and which recovered after expectant treatment, and it is possible that some of the obscure cases with intestinal obstructive symptoms that are met with from time to time are due to spasm of the mesenteric arteries. In this connexion Finney [3] records a case of his own where a girl of 20, known to be suffering from Raynaud's disease, was seen by him with the symptoms of a subacute intestinal obstruction in which he jokingly made a diagnosis of spasm of the *superior mesenteric artery*. At operation a length of blackened gut was discovered at the lower end of the ileum; three feet were resected, and the patient made an uninterrupted recovery.

(*b*) The *venous types* are divided again into ascending, where foci of sepsis are present in the pelvis or lower abdomen—such as a suppurating appendix or an infected ovarian cyst—and descending, where liver conditions, such as cirrhosis or infection, are present. An important division of the ascending cases is those cases of thrombosis of the splenic vein where splenic disease is present.

CLINICAL PICTURE.

From a consideration of the production of intestinal obstruction in the various groups, it seems evident that the mode of onset and the initial symptoms will vary. For instance, a case of embolism from a cardiac vegetation would be expected to show a history of an acute sudden onset and a rapid supervention of gangrene with symptoms of obstruction; whereas the arterio-sclerotic type might reasonably be expected to have preliminary symptoms and to run a less fulminating course. Similarly, in the venous types, a thrombosis starting in the radicles of the portal system, or a gradual occlusion of the ramifications of the portal vein in the liver spreading back to the portal vein itself, would give rise to some preliminary subacute symptoms before the onset of gangrene brought on a condition of complete intestinal obstruction.

A point brought out in the cases quoted below which seems to be of some diagnostic value is the frequency with which the onset of pain is situated in the right iliac fossa. I can find no mention of this in the literature, although it seems to be a reasonable thesis that thrombosis would be most likely to start in the furthest branches of the portal system, which, in the case of the superior mesenteric vessels at any rate, would be in the region of the ileocæcal junction. As regards the inferior mesenteric artery the rarity of the condition in these vessels may be explained by the fact that their most distal branches, the superior hæmorrhoidals, enter into communication with the systemic circulation via the middle and inferior hæmorrhoidal vessels, and also because arterial embolism is less likely to occur in the inferior mesenteric artery owing to the fact that this leaves the aorta at more of an angle and at a lower level than the superior mesenteric artery.

In the series of cases mentioned below there is no instance of occlusion from an embolus, and in no case could the onset of the illness be considered sudden or the course fulminating. The embolic cases are, of course, the most favourable, or rather, least unfavourable for operative cure, for any resection carried out on thrombotic cases is likely to be followed by a spread of the thrombosis along the vascular tree.

The late picture in this condition is the same in all types, being that of an intestinal obstruction; characteristic features are the passage per rectum, of a dark fluid consisting almost entirely of blood, occasionally a blood-stained vomit, a marked fall in temperature, and a raging thirst.

The relative frequency of the various types of mesenteric vascular occlusion differs markedly in the various series of cases published. Larson [1] in his review of 36 cases found the following percentages: arterial 39, venous 44, mixed 17; the average age of his cases was 52·2. Ross [5] found in five cases that the arterial were twice as common as the venous types. In my series a marked preponderance of the venous over the arterial varieties is found, only one (Case 3) being under the latter heading. The average age of my cases is 57, three being females and two males.

CASE RECORDS.

The following is an account of the cases :—

CASE 1.—A female, aged 59, was admitted on June 7th, 1924, with a temperature of 99° and a pulse-rate of 102. There had been a gradual onset of dull aching pain in the right iliac fossa 24 hours previously. This had not been very severe but had gradually become generalised over the whole abdomen. There was a watery vomit soon after admission. Her bowels had been opened slightly on the previous day. An examination revealed a tender mass in the right iliac fossa, and an operation was advised. When the abdomen was opened four feet of blackened ileum were resected and an anastomosis performed. The patient died seven hours later. Post-mortem examination revealed an extension of the gangrene of the gut, which was found to be due to a thrombosis of the portal system spreading distally from the liver, which was very soft, pale, and homogeneous in appearance. No other cause could be found for the thrombosis.

The thrombosis was venous and descending in this case. The symptoms were gradual in onset and began definitely in the right iliac fossa.

CASE 2.—A female, aged 66, was admitted on Jan. 18th, 1925, with a temperature of 98° and a pulse-rate of 86. Seven days before she had complained of a feeling of constriction around the upper abdomen and said she noticed a swelling of the upper left part of her abdomen. She had experienced increasing difficulty in getting her bowels open and had been completely constipated for the previous two days. She was tender all over the abdomen on examination, especially over the lower half. Two enemas were given after admission; both were successful but contained altered blood. A laparotomy was performed the following day. Nothing abnormal was discovered except a blueness of the lower ileum. No resection was performed, the abdomen was closed, and the patient died a day later. At autopsy a thrombosis of the entire portal system was discovered, the blueness of the intestines having extended, and become, in the region of the lower ileum, a definite greenish-black colour. The cause of this was found to be a universal portal thrombosis. Death, however, had been immediately caused by a left pulmonary embolus which had presumably originated in a thrombosis of the femoral vessels which was discovered.

This was a case of venous thrombosis, and is of interest in that the femoral thrombosis and pulmonary embolism point to a diseased state of the vascular system in general, manifesting itself in two different situations. The lengthy duration of symptoms—one week—is a notable feature.

CASE 3.—A male, aged 63, was admitted on Nov. 14th, 1929, with a temperature of 100° and a pulse-rate of 120. The patient complained of pain in the abdomen during the previous fortnight. The pain was dull and aching and was situated in the right iliac fossa. He had also suffered during that time from cramp-like pains in the hands and legs. He had been unable to get his bowels open for the last four days, and on examination was found to be generally distended and tender in the right iliac fossa. No lump could be felt. At operation on the following day, a length of gangrenous small intestine was found and resected, the peritoneal cavity being full of blood-stained fluid. An anastomosis was performed but the patient died the following day. Post-mortem examination revealed a thrombosis of the superior mesenteric artery.

This was a case of occlusion from arterial thrombosis, and the long history and gradual onset of obstruction are strikingly at variance with the picture portrayed by leading text-books. The cramp-like pains in the hands and feet may possibly have been due to an obliterating thrombo-angiitis of his limb vessels, pointing to a general failure of his arterial system.

CASE 4.—A female, aged 48, was admitted on April 27th, 1931. This patient had been seen in the out-patient department a week previously complaining of vague abdominal pain with some tenderness in the right iliac fossa. An X ray examination of the *alimentary tract* was made, but no abnormality was discovered. On admission, the pain in the right iliac fossa had become a little more marked and she had a temperature of 100·2° and a pulse-rate of 100. The tenderness in the right iliac fossa was still present on examination but not so marked, and very little rigidity was found. A suggestion of acute appendicitis was made, and on the directions of the surgeon in charge of the case I operated upon her the same evening. On opening the peritoneal cavity a quantity of thin serous fluid escaped. The cæcum and terminal ileum were a little dilated and a slight blueness of the gut was noted. The intestines were carefully searched for signs of obstruction; I noticed hard masses in the colon, which were taken to be concretions of fæces and barium. In the absence of any other evidence, this was assumed to be the cause of a subacute obstruction leading to the serous effusion and the slight dilatation of the gut that was present. A fibrosed adherent appendix was removed, but did not show any signs of recent inflammation. The abdomen was closed without drainage, but the following day the patient complained of pain in the lower abdomen, where she was tender and, peritonitis being diagnosed, a suprapubic incision was made under local anæsthesia. A quantity of blood-stained fluid escaped. A drainage-tube was inserted, but the woman died a few hours later. At post-mortem examination six feet of gangrenous ileum were found. The radicles of the portal vein draining the appendix and the gangrenous gut were thrombosed, the thrombosis extending up to the hilum of the liver. The spleen was enlarged to twice its normal size and its vein was thrombosed. The mesenteric arteries and the heart itself were normal.

This case comes under the heading of venous occlusion of the ascending type. Tenderness in the right iliac fossa coupled with the rise in temperature and pulse-rate pointed, I thought, to appendical disease. The slightness of the rigidity and the obstructive symptoms present were thought to be explained by the fact that the patient was past middle age, at which time it is recognised that appendicitis may present an atypical picture.[4] The length of the history is again a marked feature.

CASE 5.—A male, aged 49, was admitted on June 4th, 1931, with a temperature of 97·8° and a pulse-rate of 88. This patient walked up to hospital with a note from his doctor, who had diagnosed a subacute appendicitis. He had begun to have pain in his right iliac fossa four days previously, which had now become generalised. He had vomited once or twice during the last two days and had only had his bowels open once—the day following the onset of his pain. His history revealed the fact that he had had a thrombosis of the left leg eight years before. On examination, he was found to be tender all over his abdomen, and some central distension was observed. An operation was performed soon after admission, and large coils of blackened gut presented through a paramedian incision. Four feet of small intestine were resected but the proximal part of the gut almost up to the duodeno-jejunal flexure showed some blueness. A Paul's tube was tied into each end and the intestines drained into a Winchester by the side of the bed. Warmed normal saline was injected at four-hourly intervals into the lower tube, the patient seeming to stand the operation well and to be fairly comfortable the next morning. The following day he rapidly sank, bloody fluid drained from the upper tube, and he died 48 hours after operation. Post-mortem examination revealed an extension of the portal thrombosis right up as far as the portal fissure and a remarkably extensive blackening of the gut. The liver showed advanced multilobular cirrhosis with superadded acute fatty degenerative change and necrosis. The whole of the portal system showed a remarkable condition of diffuse thrombosis causing a gangrenous change in the whole of the small bowel. The splenic vein was also thrombosed and the spleen greatly congested. The heart showed moderate general myocardial sclerosis with coronary atheromatous degeneration. No valvular disease was present.

This must be regarded as a venous case originating in the diseased condition of the liver. Apart from the absence of valvular vegetation or mural thrombosis in the heart, the length of the history and the subacute nature of his illness indicate this, though doubtless his damaged myocardium was an additional factor in its onset. The extensive length of gut affected is explained by a process of thrombosis starting in the liver and spreading peripherally, the most remote parts—i.e., the lower ileum—being most obviously affected.

I thank the surgical staff of the Queen's Hospital for permission to record the above cases, and in particular Mr. Hugh Donovan, who suggested this article and gave me the benefit of his advice.

AMBLYOPIA:

THE EFFECTS OF KINETIC TREATMENT.

By N. A. Stutterheim, M.D. Witwatersrand,
JOHANNESBURG, SOUTH AFRICA.

In the routine examination and treatment of eyestrain patients in my practice, according to the principles laid down in my previous publication,[1] I have been struck of late by the frequent improvement in vision without correction by glasses. I reviewed, therefore, the first 200 records of these cases and the result is that in 51 of them I found an improvement of vision averaging the remarkable figure of 50 per cent.

Amblyopia has been defined as follows:

> "Amblyopia (*ἀμβλύς*, blunt) and Amaurosis (*ἀμαυρός*, dark) are terms used for partial and complete loss of sight respectively in one or both eyes. They are not used of all cases of partial or complete blindness, but have become restricted to certain forms of more or less indefinite character devoid of ophthalmoscopic or other marked objective signs."[2]

The partial loss of sight in otherwise healthy eyes—i.e., the amblyopia of the above definition—is common, far more common than may have been realised by the profesion, if, as should be done, one includes all those cases which show partial loss of sight unwarranted by the amount of refractive error present. These amblyopias, upon coming to diagnoses, are concealed—some may call it "cured"—by the correction of the refractive error found, but the actual condition, nevertheless, persists, and the moment the correcting glasses are removed the amblyopia becomes manifest. And, moreover, even with full correction of the error, one or both eyes may show a definitely diminished visual ability compared with what they ought to have if the amblyopia were removed by more suitable treatment.

Cantonnet and Filliozat, in their recent outstanding work on strabismus,[3] have shown why in very many cases it is an advantage for binocular vision that one eye should see detail less distinctly than the other, and they call this "neutralization." In order to forestall any possible confusion it should be pointed out, however, that the subject of this paper is not neutralization but amblyopia. Amblyopia connotes a partial loss—not suppression—of sight, which manifests itself whether the other eye be looking or not. A few instances may make this clear:

CASE 1.—A, aged 18, had a vision 11/20 in the right eye, and 5·5/20 in the left; the refraction was emmetropia in the right and ½ dioptre of myopia in the left. As there was eyestrain and weakness of involuntary convergence (astheno-vergence), this patient received 17 daily sittings of kinetic treatment. The result was a cure of the astheno-vergence and consequent disappearance of eyestrain, but, incidentally, the vision, without glasses, of the right eye had increased from 11/20 to 25/20 and that of the left eye from 5·5/20 to 11/20. With correction of the ½ dioptre myopia the vision of the left eye was 25/20.

Here, evidently, was amblyopia—i.e., "partial loss of sight devoid of ophthalmoscopic or other marked objective signs"—not warranted by the condition of the refraction. Until the diagnosis of astheno-vergence and the subsequent result of kinetic treatment had made the position clear, the amblyopia had been compensated by a correction with weak negative glasses (−0·75 sph.) which had "cured" the loss of sight, giving a vision of 18/20 with each eye and of 25/20 with both together. From a visual point of view, provided the spectacles prescribed were worn, the prescribing doctor and the patient could have been content, but the patient objected to the wearing of glasses. As can be seen above, no glasses are now necessary.

CASE 2.—B, aged 21. Vision right eye 5·5/20 with −2 sph. −0·25 cyl. 25/20. Vision left eye 1·5/20 with −1·5 sph. −0·75 cyl. 25/20. Eyestrain was complained of and was cured by 21 daily sittings of kinetic treatment for astheno-vergence. The vision of the left eye improved from 1·5/20 to 5·5/20.

The vision of the right eye was justifiable by its condition of refraction, consequently this was not amblyopia, but the vision of the left eye (1·5/20) was not warranted by its refraction. As this patient also objected to the wearing of glasses, the enormous benefit to her of the increased visual acuity is evident.

CASE 3.—C, aged 28, refraction hypermetropic 0·75 in either eye. Vision of right eye 17/20, left eye 22/20. After 26 daily sittings of kinetic treatment for astheno-vergence the visions were 25/20 in each eye, without glasses.

These three cases may suffice to illustrate the point under consideration. They are, I think, evidence that we have to do with "amblyopia." This evidence is, moreover, accentuated by the experience that the defect is readily cured by kinetic treatment for astheno-vergence, showing that this loss of sight is not inherent in the condition of refraction but is caused by astheno-vergence, and is curable, therefore, without and apart from correction of refraction.

The importance of the observation that weakness of involuntary convergence (astheno-vergence) is causative of some serious defect of vision may be gathered from the fact that this kind of defect, this amblyopia, is of very frequent occurrence. As already stated, I have found it in 51 of the first 200 cases treated by me on the indications of eyestrain caused by astheno-vergence. The frequency seems to indicate that a considerable percentage of civilised humanity is suffering from amblyopia in one or in both eyes, a defect which can be radically cured by appropriate treatment of its cause, in contradistinction to the spurious cure by correcting lenses. That this partial loss of sight can be, and in many cases is, overcome by the wearing of suitable spectacles is certainly a consolation and diminishes the seriousness of the condition. Nevertheless, the condition remains.

I give here, in Tables I. and II., the figures of the 51 cases referred to—viz., 38, where at the beginning and at the end of the treatment both eyes had been tested separately as to vision without glasses, and 13 other cases where only at the end of the treatment the vision of both eyes together had been tested without glasses. The omission to test the vision of each eye separately was caused by the fact that at the time I was not aware of the importance of the repetition of these separate tests after the kinetic treatment. I was wrong in thinking that only binocular sight had greatly improved by the treatment.

The figures mentioned signify so many one-twentieths of reading of Snellen's letters at distance, according to the universally used standard.

When the averages are taken, it will be seen that the right eye's vision has improved by the kinetic treatment from 15/20 to 22/20, the left eye's vision from 14/20 to 21/20, while in the 13 cases where the improved sight for the two eyes together only was recorded, the averages are 10·5/20 before and 15·5/20 after the treatment. As will be seen, the improvement in a high percentage of cases progressed from what is considered as normal vision, 20/20, to the better vision, of 22, 24, 25, 33, and in one case even to 40/20. This, I think, is an important observation, showing that many people with potentially supernormal sight suffer eyestrain (astheno-vergence) so that they only have "normal" sight. In the series of cases recorded above, 17 out of 51—i.e., one-third—are in this group. Another group of 12 had only slightly subnormal vision (17/20); six of them improved to supernormal vision. Instructive also are the figures of those who having only 11, 8, 5·5, and still lower visions, in some cases, improved to "normal" and, in one case, to supernormal (25/20) vision.

The frequency of this form of amblyopia (25 per cent. of my eyestrain cases), its high amount (averaging 50 per cent. of the actual vision), and its curability (100 per cent.) by kinetic treatment, appear to deserve attention as important indications for the routine application of this form of treatment. The medical profession, by the invention and accurate prescribing of glasses for the correction of vision, has enormously enhanced the visual efficiency and comfort of mankind but I think the time has come to take a further step. This step is to diagnose one of the main causes of partial loss of sight, and to cure the defect permanently by kinetic treatment, without in any way neglecting the correction of refraction, whenever this is indicated after the convergence has been educated to function normally.

TUMOURS OF THE SKIN

PRODUCED BY BLAST-FURNACE TAR.

BY GEORGIANA M. BONSER, M.D. MANCH.,

BROTHERTON FELLOW IN THE UNIVERSITY OF LEEDS.

(From the Department of Experimental Pathology and Cancer Research, University of Leeds.)

IN a previous paper I. Berenblum[1] demonstrated conclusively the carcinogenic property of a sample of Scottish blast-furnace tar. In a series of 150 mice, following the application of the tar to the skin of the back between the shoulder-blades, he was able to produce 26 tumours, of which three became malignant. Up to this time it had been assumed that blast-furnace tar was non-carcinogenic, as a result of the work of A. Leitch,[2] and owing to the fact that no cases of skin cancer in man arising from contact with blast-furnace tar had ever been reported. In the present communication the results of repeating Berenblum's work with four more samples of blast-furnace tar are described. Three of these tars were obtained from Scottish ironworks using splint coal, and one from an English firm using coal from a local seam.

Source of the Tars.—The charge in an iron blast-furnace consists normally of a mixture of iron ore, limestone and coke, the latter having been previously prepared from coal in coke ovens. There are, however, limited supplies of coal which is non-caking and sufficiently hard to be used directly in the charge of the furnace, usually with the addition of 5 to 25 per cent. of coke. This type of coal, known as splint coal, is almost confined to an area in Scotland. Owing to the presence of volatile matter in the coal, a quantity of tar is carried out of the furnace by the blast-furnace gas, from which it is afterwards recovered. In the blast furnace the charge is fed in periodically at the top, where the temperature is relatively low, and the coal or coke becomes slowly heated up in its gradual descent through a rising current of hot blast-furnace gas. These conditions are ideal for carrying out a "low temperature" distillation of the raw splint coal. In addition, the high oxygen content of the coal results in the production of a tar rich in oxygenated compounds, and gives to blast-furnace tar its highly phenolic character. It is also noteworthy that the total yield of tar is small, and that a considerable quantity of water is usually present.

This process is distinct from the "high temperature" distillation of ordinary gas retorts, in which the fuel is placed in a container, and is heated to bright redness from without. In the subsequent distillation of tar and gas the contact with red hot surfaces markedly alters the character of the tar constituents. Gas tar has long been known as an active carcinogenic agent.

Of the three Scottish tars used in these experiments, the actual amount of coke added to the splint coal in the charge in the case of No. 1 was 15 to 17 per cent.; in the case of No. 2 it was 25 per cent. This latter tar was dehydrated before it was delivered to the laboratory. Scottish tar No. 3 contained a large quantity of water, the excess being decanted off before use. In this case 10 per cent. of coke was added to the burden of the furnace. The furnace from which the English tar was made was charged with 75 per cent. of coal from a local seam and 25 per cent. of coke.

EXPERIMENTAL PROCEDURE.

Sixty mice were used for testing each sample of tar. The hair was clipped away with curved scissors from a small area of skin in the region between the shoulder-blades, and the tar was applied bi-weekly for the first 14 weeks, and thereafter once weekly. This change in the frequency of the tar applications was necessitated by the rather marked tendency to ulceration of the skin exhibited by many of the mice. The experiment was continued for 56 weeks, by which time all the mice had died.

In the Table are recorded the results obtained with three samples of Scottish blast-furnace tar and one sample of English tar. An ether extract of the latter, prepared in the following manner, was also employed. The tar was treated with lime, and then extracted with ether in a Soxhlet apparatus. The ether was evaporated, and the residue was used for application to the skin. Previous experience in this laboratory had demonstrated that the carcinogenic power of a gas tar could be considerably increased by this method.

---

[1] THE LANCET, 1930, ii., 1344.

[2] Brit. Med. Jour., 1923, ii., 1

In the case of the three Scottish samples, the first warts appeared at the sixteenth week, and totals of 7, 10, and 8 animals bearing tumours were finally obtained respectively. Of these, the tumours became malignant in three animals. For comparison, the figures of Berenblum are also quoted. He obtained 26 tumours in a total of 150 mice, two-thirds of which received bi-weekly applications of the tar for the whole period of 38 weeks, and one-third of which received weekly applications for 32 weeks only. Three of his tumours became malignant. These results are remarkably similar to those obtained in the present experiment, even allowing for the differences in experimental technique. In the case of the crude English tar, the first wart appeared at the twenty-first week, in comparison with the twelfth week when an ether extract was used. Eight and 24 animals finally bore tumours respectively. Of these, none exhibited malignant changes after the application of the crude tar, but nine became malignant when the ether extract was used. Rather more than 50 per cent. of the surviving 25 animals bore tumours at the thirtieth week. Using a potent gas tar it is usual to obtain the 50 per cent. level between the eighteenth and twenty-first week of the experiment.

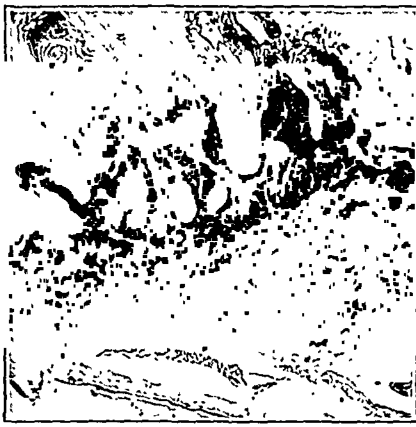
„ III...	60	16	8	4	1
English ..	60	21	8	3	0
Ether extract of English	60*	12	24	16	9

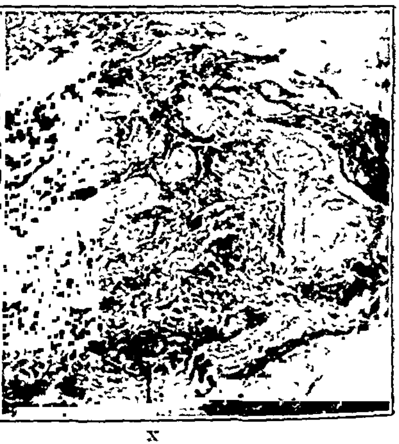
* At 30 weeks there were 25 survivors and just over 50 per cent. of these bore tumours.

FIG. 1.



(Mouse No. 9. Scottish II.) Simple papilloma of the skin of the back produced after 35 weeks' application of Scottish blast-furnace tar. (× 25.)

FIG. 2.



(Mouse No. 6. Scottish III.) Squamous carcinoma of the skin of the back after 54 weeks' application of Scottish blast-furnace tar. X indicates position of invasion of muscle by tumour. (× 80.)

Fig. 1 illustrates a typical early wart produced by blast-furnace tar. Keratinisation of the more superficial part of the tumour is usually well marked as in this case.

The malignant tumours show the structure of squamous carcinomata invading the muscular layer of the skin, and are usually surrounded by a well-marked acute and chronic inflammatory reaction (Fig. 2). One malignant tumour, obtained after 47 weeks of application of ether extract of English tar, consists of a mass of mononuclear round cells invading the adjacent muscle and fat, often seen in mitosis, and metastasising to local lymph glands.

CONCLUSIONS.

From these results it is possible to conclude that blast-furnace tar obtained from a variety of sources is able to produce malignant tumours in mice. It is less active than the gas tar employed in this laboratory, but its carcinogenic properties can be enhanced by extraction with ether. Berenblum pointed out that his sample of blast-furnace tar contained a large quantity of water. Of the samples used for these experiments, Scottish No. II. was dehydrated before receipt, and produced two malignant tumours in 60 mice. Scottish tar No. III. also produced a malignant tumour. This tar contained an excess of water, which was decanted off before use. So that Berenblum's contention that the water content of the tar has no relation to its carcinogenic properties receives strong support. If applied too frequently blast-furnace tar produces ulceration of the skin, but its toxic effects are not well-marked, as was demonstrated by the fact that some of the animals survived weekly applications of the tar for 56 weeks.

With regard to the industrial aspect and the possibility of skin cancer in man arising from contact with blast-furnace tar, it appears that the workers in the ironworks do not handle the tar in the same way as the workers employed by producers of gas tar, pitch, and paraffin. In the first place the yield of tar, as stated above, is small. Secondly, blast furnace tar is regarded as a waste product and is disposed of without further handling. These considerations, together with the fact that blast-furnace tar is not a potent carcinogenic agent, are sufficient to explain the absence of epitheliomatous ulceration in blast-furnace tar workers, and it may be postulated that this tar would be carcinogenic for man as well as for mice given the right conditions for its contact with the skin.

BIRMINGHAM CONTRIBUTORY SCHEME.—Last year the membership of the Birmingham Hospital Contributory Scheme increased by 7382 to 411,584, and the amount collected increased by £2381 to £202,387. In four years the scheme has raised £746,000.

CLINICAL AND LABORATORY NOTES

PERIPHERAL NEURITIS AS A COMPLICATION OF ANGIONEUROTIC ŒDEMA.

DESCRIPTION OF A CASE.

BY W. MACKAY, M.D., F.R.F.P.S. GLASG.,
PHYSICIAN TO THE OUT-PATIENT DEPARTMENT, ROYAL INFIRMARY, GLASGOW.

IN a recent paper Dr. I. M. Allen[1] describes a case of "brachial neuritis and amyotrophy" associated with serum-sickness, and reviews 42 reported cases in which disturbance of the nervous system has followed serum treatment. Most of those reported have appeared in France, where it is recognised that the therapeutic injection of serum may produce neuritis. The following is a description of a case of angioneurotic œdema in the course of which peripheral neuritis developed. It seems to belong to the same category as those described by Allen yet, prior to the onset of his illness, no serum had ever been given to the patient. Such cases are extremely rare.

A man, aged 21, a bus conductor, was admitted to Prof. W. K. Hunter's wards at the Royal Infirmary, Glasgow, on Dec. 1st, 1931.

History.—He had always been well until the previous August, when suddenly he had an attack of dyspnœa resembling asthma. The difficulty in breathing was worse at nights but in a day or two it gradually passed off and the patient resumed work although he did not feel in good health. About the beginning of September he began to have transient and recurrent swellings in the eyelids and over the temples and cheeks. A little later, over various parts of the body, hot and itchy "red lumps" came and went and in the middle of October swellings of an urticarial type appeared, disappeared, and reappeared every few days. The nature of the "red lumps" is unknown. A week before admission to hospital he had shooting pains, but no swelling, in his left forearm, and within a few days he was unable to extend the left wrist. The patient denied the possibility that he had lain on his arm or that he had otherwise injured it. The family history and the patient's habits and environment did not seem to bear any relation to his illness.

On admission there was slight puffiness in the region of the eyes. The skin over the neck and trunk was covered with urticarial swellings of a dirty green hue surrounded by a reddish margin. Some were as large as the hand, others much smaller. There was no complaint of pain in the arm, but the patient was unable to extend the left wrist and he had difficulty in abducting the index, ring, and little fingers from the middle finger. He was able, however, to extend the two distal phalanges of the fingers when the proximal phalanges were flexed. He could bend the elbow but the supinator longus did not seem to take any part in the movement. The biceps and triceps jerks were feebly present. It was apparent that the extensors of the wrist and fingers, the supinator longus, and the interossei were the muscles involved. Appreciation of light touch, temperature, and pain was diminished over the area of the hand supplied by the cutaneous branches of the ulnar nerve. No other lesion of the nervous system was detected, and beyond the presence of numerous rhonchi in the lungs no abnormality was found in the other body systems.

Course of illness.—In from seven to ten days the urticarial eruption had almost gone but smaller patches recurred from time to time, the last patch being noted on Dec. 21st. The most prominent feature of the illness was the frequent occurrence of transitory œdematous swellings in the eyelids and lips, and over the temples and cheeks. On one occasion an œdematous swelling was observed in the anterior abdominal wall and on another, swelling of the tongue was associated with dysphagia. Pain and swelling were present in the right wrist-joint on Dec. 16th and 21st.

In the left arm, atrophy of the extensors of the wrist and fingers, the supinator longus, the interossei, and the muscles of the hypothenar eminence gradually developed and the patient became unable to extend the distal phalanges of the little finger. Electrical tests were applied, and it was reported that the hypothenar group of muscles gave no response to faradism, the interossei gave only a weak reaction, while the extensors of the wrist responded fairly strongly. The remaining muscles of the hand and arm reacted normally. All the muscles of the affected limb responded strongly and quickly to galvanic current.

Throughout the stay in hospital the temperature ranged between 98° and 100° F., although on several occasions shortly after admission to hospital it reached 101° F. At first the pulse-rate was about 130 but it settled later to between 90 and 100. There were no attacks of asthma. Three carious teeth were removed, but no other septic focus was discovered. The bleeding time was within normal limits. While urticaria was present the blood platelets numbered 1,118,000. The erythrocytes averaged about 4,400,000, and there was a degree of hæmoglobinæmia (48 per cent. to 60 per cent.). The leucocytes varied between 6200 and 7800. The Wassermann reaction of the blood was negative. The urine all through was free from abnormal constituents. Dr. C. M. Fleming found the proteose in the urine to be slightly increased in amount, but there was no cutaneous reaction to this substance on the application of scratch or intradermal tests.

Three and a half months after admission power was slowly returning to the affected muscles although atrophy was still present. The biceps and triceps jerks were active. There was still a little difficulty in appreciating tactile, thermal, and painful stimuli over the ulnar side of the hand. The recurring œdema did not respond to treatment with calcium lactate, parathyroid, horse serum, blood transfusion, or marmite, but the general health of the patient was improved and, as he was becoming hospitalised, he was discharged.

The characteristic features of this case are: transient and recurring, localised yet "wandering" œdema, urticaria, slight febrile disturbance, and occasional arthritis. They are very similar to those of serum-sickness. This disease is an expression of anaphylaxis and it is characterised mainly by urticarial swelling, œdema of various parts of the body, arthritis, mild pyrexia, and general malaise. In Allen's case and in most of those reviewed by him the signs of a neural lesion were associated with urticaria. The connexion between urticarial œdema and the disturbance of the nervous system in serum-sickness is so close that an ætiological relationship can be inferred. It is not surprising therefore that similar disturbance may arise in the course of angioneurotic œdema or, as it is sometimes called, "giant urticaria." Such a complication is extremely rare, although symptoms of cerebral origin—epileptiform convulsions, hemiplegia, deafness, and recurring attacks of blindness—have been reported (F. Kennedy[2]). No reference is made to them in well-known British, American, or French text-books.

In the case just described, the main features of the illness were established for at least two months before there was any evidence of involvement of the nervous system. A peripheral neuritis then developed, the musculospiral and the ulnar being the nerves affected. Both were implicated below the level of the elbow, and the evidence suggests that each was separately involved. In four of the cases reviewed by Allen, the musculospiral was implicated and in two of these the lesion was distal to the triceps branch. The disturbance in the nervous system in this case of angioneurotic œdema is similar to some of those occurring in serum-sickness. This is to be expected, since angioneurotic œdema, like serum-sickness, is an expression of anaphylaxis, the essential difference being that in serum-sickness the anaphylactin is known while in angioneurotic œdema its source and nature are frequently matters for conjecture. Further, the symptomatology of each is similar. The common anaphylactic origin suggests a common pathogenesis for the lesions occurring in the nervous system in the two conditions. Allen favours the view that in serum-sickness "local and general œdema" explains the paralysis of single nerves. It is easy to suppose that the change which permits the transudation of serum through the capillaries of the skin and mucous membranes will also take place within the internal structures of the body. In the case under discussion, it is possible that a localised œdematous swelling in the connective tissues of the affected nerves brought about a compression paralysis.

---

[1] THE LANCET, 1931, ii., 1128.

[2] Arch. Neurol. and Psychiat., 1926, xv., 28.

It must be concluded therefore that this case of angioneurotic œdema with peripheral neuritis belongs to the same category as those of serum-sickness, showing similar disturbances in the nervous system.

I gratefully acknowledge my indebtedness to Prof. Hunter for permission to publish this case.

RETENTION OF URINE IN A CHILD, DUE TO AN APPENDIX ABSCESS.

By H. Lovell Hoffman, M.B. Camb.,

CASUALTY OFFICER, ROYAL NORTHERN HOSPITAL, LONDON.

A BOY, aged 4 years, was admitted to the Royal Northern Hospital on July 8th, 1931. A week before admission he was said to have had an attack of abdominal pain, during which he vomited twice. After this there was difficulty in micturition, the urine being noted to be dark and scanty. The child had passed no urine at all during the 24 hours before admission, and the bowels had not been open for two days.

State on admission.—Pale child, in no distress. Temp. 102°. Pulse-rate 126. Resp. 23. A swelling was found rising out of the pelvis, dull to percussion, and apparently a distended bladder. There was no abnormality in the penis, the child having been circumcised one year previously. Per rectum an indefinite tender swelling was felt on the left side. The heart, lungs, and central nervous system were normal.

On admission the child was catheterised twice, 9 oz. and 3 oz. of urine being obtained in scanty drops. Great difficulty was experienced in passing the catheter, a fine gum-elastic one being used on the second occasion. After catheterisation the abdominal swelling remained. The urine was acid with a trace of albumin and a few epithelial cells. Radiography of the urinary tract revealed no evidence of calculus.

Progress.—The child was catheterised daily from admission, with results similar to those at the first attempt, the daily measure of urine being 10–12 oz. On July 12th he passed 3 oz. of urine naturally. He complained of intermittent pain in the left side and in the left leg. Mucus was noted in the stools.

On July 13th the temperature was 99·8° and the pulse-rate 130. Tongue furred, lips dry, fæcal odour in breath. Leucocyte count 32,000 per c.mm., 61 per cent. polymorphs.

On July 14th intravenous pyelography was performed, 12 c.cm. of abrodil being used. A bilateral hydronephrosis and hydro-ureter were seen. A cystogram showed a normal bladder outline. A cystoscopy was performed by Mr. Kenneth Walker under general anæsthesia, the interior of the bladder being found to be normal. The bladder was emptied and a bimanual examination was carried out. A swelling could be felt, extending up to the umbilicus, which could be pressed down on to a finger in the rectum, and appeared to be cystic in character.

On July 15th the blood-urea was found to be 21 mg. per 100 c.cm. A diagnosis of pelvic suppuration was made, and it was decided to explore the abdomen.

On July 20th an attempt, during the morning, to pass a catheter proved unsuccessful. By 2 P.M. the temperature had risen to 103·5°. (The child had been catheterised daily up to this time.)

First operation.—At 3 P.M. Mr. L. E. Barrington-Ward opened the abdomen through a left subumbilical paramedian incision. The bladder was distended and caused considerable difficulty throughout the operation. The intestines were firmly fixed to the posterior surface of the bladder and the cæcum appeared to be involved in the mass of adhesions. The appendix was not seen. These adhesions were separated with the finger right down to the neck of the bladder, and in this situation a cavity was opened, from which welled up 2 oz. of foul yellow pus arising, apparently, from a low pelvic appendix. The abscess was drained and the abdomen was closed, a catheter being tied into the urethra. The patient stood the operation well; by the next day the catheter had drained 12 oz., and there was not much discharge from the abdominal wound. On July 22nd the catheter was removed, and the child passed urine naturally into the bed.

Further progress.—The wound later discharged fæcal material, but was dry on August 6th, and from this date convalescence was uneventful. The child was at first incontinent of urine, but eventually regained full control of micturition. During the next six months he was seen several times. He had one attack of acute tonsillitis, but was otherwise well. He was readmitted on Dec. 13th for appendicectomy.

Second operation (Dec. 14th, by Mr. Barrington-Ward).—Incision right paramedian. On opening the abdomen, a mass was felt in the right iliac fossa consisting of cæcum and small intestines matted together by adhesions. These were separated, and in so doing a residual abscess was opened, containing 1 drachm of inoffensive pus which was sterile on culture. The appendix was found lying in the abscess cavity and running down into the pelvis. It was found, on separation, to be about 2 in. long and ½ in. in diameter. It was removed by the usual technique and the abscess cavity was drained.

After the operation the child developed broncho-pneumonia, but made a good recovery, and was discharged fit on Jan. 10th, 1932. An intravenous pyelogram taken on Jan. 7th showed normal renal pelves and ureters.

Pelvic suppuration is a rare cause of retention of urine, and the possible mechanisms causing the obstruction may be considered under two heads—mechanical and nervous.

It seems difficult to believe that the collection of pus which was found could, by its increased tension alone, occlude the urethra; the outer walls of the abscess, consisting of intestines and adhesions, would be very much more compressible than the first part of the urethra surrounded by the prostate. There are, however, certain reflexes between the internal sphincter, the bladder musculature, and the surrounding organs. For example, the reflex between the bladder and the rectum is well known. A full rectum will cause difficulty in micturition, while a distended bladder will inhibit defæcation. The reflexes are mentioned by Janet,[1] and some authorities, for example, Li Virghi,[2] believe that the retention in cases of enlarged prostate is due to some similar effect. One can then easily imagine the congestion and induration surrounding the abscess in this case, causing irritation of the nerves and reflex spasm of the sphincter.

I wish to thank Mr. Barrington-Ward and Mr. Kenneth Walker for allowing me to publish this case.

"ROYAL" HOSPITALS AND HOUSE SURGEONS.—The annual meeting of subscribers to the Bolton Infirmary and Di[illegible]sk for authority to prefix the word "[illegible] The grounds for the application appear [illegible] would "add to the importance of the [illegible] it would remove a difficulty that has been experienced in obtaining house surgeons, "the medical profession being firmly convinced that the addition of the word 'Royal' would attract the better class of medical student."

OUT-PATIENTS IN MOTOR-CARS.—At the annual meeting of the Aberdeen Royal Hospital for Sick Children, the Earl of Caithness, the president, complained that the extended medical services of the institution were being taken advantage of by a class of people for whom it was not originally intended. It was not unknown, he said, for patients to arrive in private cars which waited during their treatment and took them away afterwards. Since 1928 in-patients have increased from 1059 to 1744, and out-patients from 3900 to 6478. On the average an out-patient pays five visits.

REVIEWS AND NOTICES OF BOOKS

A System of Bacteriology in Relation to Medicine.

Vol. IX. By Various Authors. Edited by P. FILDES, M.B., B.Ch., O.B.E., and Prof. J. MCINTOSH, M.D. London: H.M. Stationery Office. 1931. Pp. 364. 21*s*.

THIS volume is the last of the "System of Bacteriology in Relation to Medicine" published under the auspices of the Medical Research Council. Entirely different in its scope, it is a worthy successor to its predecessors. It is devoted entirely to technique and no discussion of general principles or of theoretical considerations finds a place in its pages. To be severely practical has been the aim of the editors.

In their prefacing note they abjure any attempt to cover the whole of the vast field of bacteriological technique and they adopt as their guiding principle the criterion of results. "An editor," they write, will "realise that someone he knows is notoriously capable of reproducing by one method the results supposed to require several hundred," and this has been the basis of selection exercised. This method of selection may entail the omission of methods which in many hands have worked well, but hardly in any other way is it possible to blaze a clear and definite trail through such a tangled jungle as that of present-day bacteriological technique. To define such a clear and easily followed path has been the aim of the editors and in it they have succeeded admirably. Besides such general matter as concerns the staining of micro-organisms and the preparation of culture media, full descriptions are given of many methods necessary for the study of the metabolism of bacteria, for the majority of which laborious reference to the periodical literature has up to the present been necessary; thus concise instructions are given for the identification and estimation of bacterial metabolites, for estimation of the pH, of electric charge, and on many other matters. To the investigator in the higher branches of bacteriological research such a collection of technique as this must save untold time and trouble; to the routine laboratory worker faced with the setting up of an unfamiliar technique the book will also be a boon; to such the sections on the care and breeding of laboratory animals will be of service.

The opening sections by a happy inspiration are devoted to a description of two of the most up-to-date laboratories in the British Isles, the Sir William Dunn School of Pathology at Oxford and the Department of Pathology of the University of Cambridge. It is probable that few readers of the book will be called upon to plan university laboratories, but many may be called upon to build up laboratories on a smaller scale and to survey the ideal even though unattainable is a salutary exercise. To those called upon to plan and equip even the smallest laboratory the details of treatment of benches, plumbing, water-supply, and so forth given in respect of the Cambridge department will be of the utmost value.

The absence of some such standard work as this has long been something of a reproach to English bacteriology. Its appearance draws attention to the equal need for some such authoritative compendium covering the whole field of pathological technique, particularly in its application to clinical medicine.

A Course in Practical Biochemistry.

Second edition. By A. T. CAMERON, M.A., D.Sc. Edin., F.I.C., F.R.S.C., Professor of Biochemistry, Faculty of Medicine, University of Manitoba; and FRANK D. WHITE, A.R.T.C., Ph.D. Edin., F.I.C., Assistant Professor of Biochemistry in the Faculty. London: *J. and A. Churchill.* 1932. Pp. 237. 8*s*. 6*d*.

THE appearance of the second edition two years after the first indicates the popularity of the book. Prof. Cameron has done great service in producing two works which are of the very greatest assistance to the teacher of biochemistry. His text-book has been referred to in these columns, and it is with pleasure that the present new edition is noted.

The course here described is much more elaborate than that given to most English medical undergraduates. Those familiar with Canadian and American medical education will remember that much more time is devoted to practical laboratory work in physiology and biochemistry there than here, the less intensive study of anatomy making this possible. The book is divided into two main sections, Part I. dealing with qualitative, and Part II. with quantitative and clinical procedures. Part I. contains all the details to be found in most English courses of practical biochemistry, such as tests for proteins, fats, carbohydrates, and enzymes. Part II. is by far the more interesting from the point of view of the English teacher. In most medical schools very little quantitative biochemistry is done; for example, the use of the colorimeter for the analysis of blood, the performance of gastric analyses, the estimations of alkali reserve, and of basal metabolic rate are only just beginning to be taught. The subjects are treated very clearly, and any student after passing through a department of biochemistry, working conscientiously through the course described, would be well equipped. The student will find the information here set out of the greatest value right through his medical course, and if he buys this book will not have to supplement it later with works on chemical pathology or clinical chemistry.

Chirurgische Indikationen.

By Prof. Dr. KARL RESCHKE. Oberarzt der Chirurgischen Universitäts Klinik, Greifswald. First (General) Part. Berlin: *F. C. W. Vogel.* Pp. 357. R.M.22.

SOME years ago in France appeared a book on "Surgical Therapeutics" by Leriche and Lecène, which approached the subject from a somewhat original standpoint. They assumed every surgical problem to be essentially an intellectual one. The plan resulting from this mental deliberation requires a special technique for its execution, and operative procedures were excluded from consideration. Prof. Karl Reschke has for Germany written one part of a book to a very similar design. The volume before us is concerned with what is known as general surgery. But it is more than that, for, to avoid overlapping, the consideration of much usually relegated to the special part is dealt with here: a welcome innovation and a satisfactory arrangement. It is true that much of the knowledge offered is set out in general text-books, but where it is unencumbered by pathological descriptions and accounts of operations, far more stress can be laid upon the evidence for and against the various methods of therapy, and far more space devoted to these important considerations. If the reader should want to know more exactly on what the judgments here recorded are based, there is an excellent bibliography which will refer him to the original sources.

The whole book is well conceived and very well executed. It is interesting to read and contains readily accessible information, to obtain which otherwise would often require an arduous search of the literature. As examples we can ascertain the prospect of gangrene after ligation of any of the main arteries, the probable results of tendon suture, and the indications for and disadvantages of avertin narcosis, while there are excellent summaries of the position of spinal anæsthesia, the different methods of administration of tetanus antitoxin, the value of X rays in lymphatic gland tuberculosis. In his preface Prof. Reschke, while voicing the hope that his book may be of use to students and junior practitioners, modestly observes that the experienced surgeon will gain *nothing new from it but will only be confirmed in his* agreement with or dissent from its expressed views. But there seems little doubt that many experienced surgeons will read the book with considerable interest, and scarcely with no profit at all.

The feeling amongst some physicians that the surgeon is too much obsessed with his technique is belied by such works as this. Indeed amongst modern surgeons there is rather the danger of underestimating the extreme importance of operative skill. The substance of this book is the purely mental processes of surgery, hence there is no need for illustrations, and there are none.

Text-book of Histology.

By EUGENE C. PIETTE, M.D., Pathologist and *Director of the Laboratory of the West Suburban* Hospital, Oak Park, Illinois. Philadelphia: F. A. Davis Company. 1931. Pp. 466. $4.50.

IN recent years there has been a revival of interest in histology, especially in the United States. Dr. Piette's contribution to the rapidly growing collection of text-books is a reliable work in so far as the reading matter is concerned. It presents concise and not too detailed descriptions of structure, accompanied by short notes on function. Heavy type has been liberally interspersed to facilitate revision work. The matter presented is complete and up to date; research work on histology is adequately reviewed and recent advances in the subject are clearly summarised. The names of many authors are cited, and these are gathered together in an "authors index" at the end of the book; but this list will give little help to the student, since no bibliographical references to their works are supplied. The feature of the book which calls for adverse criticism is the illustrations. These are nearly all borrowed from other works. Some of them are bad and many are inappropriate to the text. For example, on page 208 occur the following lines on the thyroid follicles: "They are lined with one layer of cuboidal (seldom flat or columnar) epithelium; the cells are united by terminal bars (Fig. 136)." The illustration of the thyroid gland referred to (which, incidentally, we would not accept as a true representation of the normal thyroid) is of too low magnification (× 80), to demonstrate individual cell structure, and terminal bars are not mentioned in the legend to the picture. Another unfortunate feature is that, when references are made to figures placed at distant parts of the boo the number of the figure is given but not always th number of the page. This would be inconvenien even if all the numbers had been carefully confirmed but this has not been done. For example, referenc is made on page 311 to Fig. 206, which ought t represent a "corpusculum renis" but which i fact represents a ureter of an executed convic There are other errors; for example, the XII. in th last line of page 201 should read X. The style i strongly American and words like "cellulipetal, "increts," and "excrets" are freely used. In spit of these inconveniences the book makes pleasan reading.

The Psychology of Children.

1. *Psychology and Psychiatry in Pediatrics.* Ne York City: The Century Company; London D. Appleton and Co. 1932. Pp. 146. 7*s.* 6*d.*

2. *The Robinsons.* By THOMAS E. LAWSO L.R.C.P., L.R.C.S. Edin. London: The C. W *Daniel Co. 1932. Pp. 44. 1s.*

1. THIS is the report of a subcommittee of th White House Conference, and it is not made clea to the reader how the discussion came about, of wha personnel the various committees and subcommittee were composed, what were their terms of referenc or to whom the report is addressed. This make the task of the reviewer difficult because to allud to omissions might mean that the reproach referre to matters which were never intended to come u for discussion. We may draw attention with approv however to the series of conclusions to be found o page 42. Whoever came to these conclusions, an with whatever purpose in view, there can be no doub of their soundness. Adequate care of children cann be given without intelligent attention to the intellectual and emotional difficulties. The vie *that the doctor without being an expert can acqui* "psychiatric intelligence" is supported by insisten upon his exhibition of "patience, curiosity, toleranc and almost invincible optimism." The su committee believe that if doctors in large numbe acquire "psychiatric intelligence," and becom sensitive to the educational implications of the situ tions which arise in their practice, expert psychologis would be more often called to advise in difficult case to the great advantage of home and school training.

2. Character studies of a family epitomise th influence of environment on the growing child durin the first few years of his life, thus indicating th responsibility which rests on all whose duties brin them into close contact with children. The pamphl is the story of five ordinary people told fluently an humorously, and as Sir Arbuthnot Lane says in prefatory note, the result is five tragedies. T author has limited himself, or nearly, to depicting th influence of one factor in the child's environment-namely, that of place in the family—and he show cleverly how the personalities of the parents inte act to the benefit or the detriment of their offsprin when favouritism or coldness is manifested. Th Robinson circle consists of a hypochondriac, ineffecti father, a capable conceited mother, an elder so whose moral rectitude is outraged by the behavio of an elder daughter, who might have been describe indelicately in a monosyllable, and a younger so the baby of the family, who develops into a ver disagreeable fellow for reasons well set out. The is much acute observation in this unpretentious litt volume.

BELLE VUE SPA AND HOTEL

TREFRIW, NORTH WALES

The combination of medical treatment and comfortable residence amid beautiful scenery offers great attraction to visitors as well as patients.

Special facilities are provided for those requiring treatment.

Thirty bedrooms, magnificent lounges, billiard room, tennis court, eight and a half miles of salmon and trout fishing, and golf courses within easy reach. The new bath and treatment rooms within the Belle Vue Spa's grounds, recently opened by an eminent surgeon, are equipped with the most up-to-date apparatus for electrical treatment under medical supervision.

The chalybeate baths for Ladies and Gentlemen are situated on each side of the treatment room.

The Belle Vue Spa sulphur-iron water (ferrous sulphate), described by medical men as the purest and most highly concentrated in the world, is collected from the living rock according to medical advice, so as to prevent any air coming in contact with the iron water.

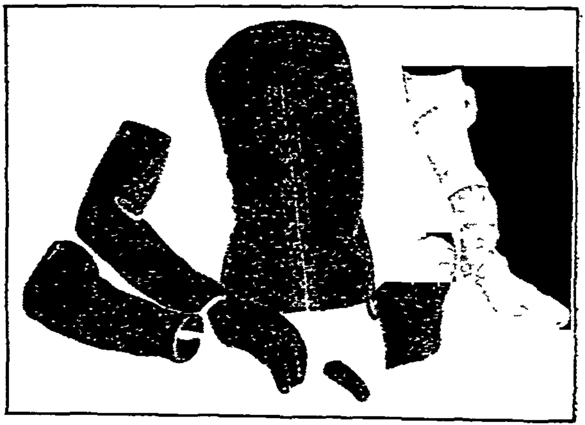
Sufferers from Rheumatoid Arthritis or Osteo Arthritis, who have been bed-ridden for months or years and want to walk again without pain, can avail themselves of the Hœfftcke Ambulatory Extension Treatment under medical supervision.

This treatment has been favourably commented upon by many eminent medical men in their books and also in the medical papers.

For full particulars apply The Secretary, Belle View Spa, Trefriw, N. Wales.

TWO FURTHER ADVANCES BY THE MAKERS OF ELASTOPLAST

Half spread Elastoplast. Only the first turn of plaster touches the skin. Perfect support and compression for Varicose Veins, and all injuries to joints and limbs.



50% lighter than any other Plaster of Paris Bandage. Cleaner and easier to apply. Moistening takes only 5 seconds. Setting, 5 minutes or longer as required.

gr. $\frac{1}{600}$ ($\frac{1}{10}$ mg.)

Digitalin Granules, "A. & H.," a British preparation, consist of the *Digitaline cristallisée* of the French Pharmacopœia. This substance is the most active principle of digitalis leaves. and, because of its reputation for uniform activity, it has long been popular, particularly on the Continent. Its use is recommended by high authority in cases where galenical preparations of digitalis have failed.

For Prescribing:
In tubes, containing 40 granules, 2/6 each
For Dispensing:
In bottles, containing 250 granules, 12/6 each
Subject to the usual professional discount.

Descriptive literature and clinical trial sample will be sent post free on application.

THE LANCET.

LONDON: SATURDAY, APRIL 9, 1932.

CHRONIC DUODENAL STASIS.

MUCH has been written, but not so much is known, about chronic duodenal stasis. There are big differences of opinion about it. In most English text-books, for instance, it receives scant mention, and the impression is conveyed that it is rare. In France, on the other hand, they think it important; and in a large new manual of medicine and surgery we find more space devoted to "chronic incomplete stenosis of the duodenum" than to duodenal ulcer itself. According to a recent review by Prof. F. DE BEULE, of Ghent, and others,[1] the condition, though little recognised, is actually common and of corresponding importance and interest. Its existence was suggested by ROKITANSKY as long ago as 1842, and later by GLÉNARD in 1887, but it is only in recent years, with further advances in radiology, that more complete investigations have made it possible to fill in the clinical picture. The duodenum, it may be recalled, is normally fixed by the peritoneal reflection and some three or four "ligaments"; it is crossed by the mesocolon and the root of the mesentery carrying the superior mesenteric artery. Anatomical abnormalities, either congenital or acquired, might thus mechanically compress or obstruct it, and lead to a condition of stasis and dilatation. Of such causes DE BEULE gives numerous examples, as for instance, congenital bands and acquired adhesions around the duodenum following inflammation from cholecystitis, pancreatitis, or even more distant infection such as appendicitis. The latter he suggests acts through a lymphatic spread and is of particular importance. Other causes of duodenal stasis are grouped under the headings of: (1) duodenal ileus, or paralysis due to inflammatory processes such as duodenal ulcer; and (2) stasis following disordered balance of the autonomic nerves (vagus and sympathetic). These groups are rather less definite in their ætiology. H. F. SHATTUCK and H. M. IMBODEN,[2] who report 46 cases in which the diagnosis of chronic intermittent duodenal obstruction was made, considered that bands and adhesions or pressure from the mesenteric pedicle were the two most usual causes. Other workers have found no mechanical obstruction in some 30 per cent. of cases of true megaduodenum, and SCHMIEDEN and KRAAS[3] not long ago reported the operative cure of two cases in which the duodenum was as large as the colon, although there was no apparent obstruction.

Two years ago REGINALD MILLER with H. C. GAGE[4] drew attention to chronic duodenal ileus in children associated with enlargement of the stomach. In describing their own series of cases they mentioned the fact, as noted by other observers, that adults with chronic duodenal ileus might give a history of symptoms during childhood which had ceased for many years during adolescence. In children the main symptoms, as described by MILLER and GAGE, are anorexia and vomiting with malnutrition and lack of growth; there is a comparative absence of pain in the abdomen except immediately before vomiting. In the adult the typical symptoms are described as being cyclical crises of abdominal pain with bilious vomiting and a sensation of weight and distension in the epigastrium; the absorption of toxins from the duodenum gives rise to such general symptoms as headache after meals, and loss of weight and energy. Various groups of symptoms are said to simulate cholelithiasis, appendicitis, and simple duodenal ulcer. Radiographically, by which means the diagnosis has finally to be made, the main features of chronic duodenal stasis are given as: delay in passage of the meal through the duodenum (according to DE BEULE and DE WITTE longer than 15 seconds), dilatation of the duodenum, and the presence of abnormal peristaltic and antiperistaltic waves. Treatment must be mainly directed to the cause. Often it must be surgical, and duodeno-jejunostomy is recommended as giving excellent results in many cases, though other forms of operation have been proposed and practised. In children, as MILLER points out, medical treatment is as a rule desirable, since spontaneous improvement seems to take place at the age of about 5 years. This treatment should aim at lessening the bulk of the diet and the frequency of the feeds—the object being to discourage any associated enlargement of the stomach. Even in adults many clinicians advise a thorough trial of medical measures. Of these, postural treatment is regarded as important and considerable relief is obtained by adopting the knee-chest position or by lying on the chest or on the left side. The diet advised is similar to that generally in use for gastric ulcer. Abdominal massage and the use of a suitable belt are also recommended. If, however, we are to believe that a mechanical obstruction is the most frequent cause, it is hard to see that non-surgical treatment can be an effective cure, especially in view of the reported success of surgery even in non-obstructive cases.

Cases of congenital mechanical obstruction of the duodenum are rare, and actual duodenal stenosis, from whatever cause, is certainly less common than pyloric stenosis. But minor degrees of "ileus" may perhaps be commoner than is generally realised. There is a large group of chronic dyspeptics offering vague symptoms, with discomfort and nausea after meals and a feeling of distension in the epigastrium; and in many of these cases no evidence of gall-bladder or other abdominal disease can be found. In some of them attacks of profuse biliary vomiting occur periodically, closely resembling migraine. Of SHATTUCK and IMBODEN's patients a large number had suffered from "bilious attacks" even since childhood, sometimes with unilateral headaches; and more than half had had their appendices removed without relief. Such a condition is apt to be labelled nervous indigestion or visceroptosis, but the patient may in fact be suffering from mild duodenal stasis. The accompanying symptoms of fatigue, headache, and the like, so often encountered in these cases, could certainly be produced more easily by absorption of toxins from the small intestine than from the large, and a duodenal "constipation" must be a far more serious thing than colon constipation. The question is undoubtedly one of real practical importance and it is to be hoped that further work, especially radiological, may show to what extent duodenal stasis may really be a cause of chronic indigestion. If we are to believe the French authorities we must regard it as one of the commonest causes of otherwise unexplained digestive symptoms. But its true incidence is at present the most doubtful thing about it.

WATER METABOLISM AND EPILEPSY.

In their comprehensive monograph on epilepsy W. G. Lennox and S. Cobb [1] attribute the following statement to Hippocrates or one of his pupils :—

> "But whoever is acquainted with such a change in men and can render a man *humid or dry*, hot or cold by regimen could also cure this disease (epilepsy), without minding purifications, spells and all other illiberal practices of a like kind."

Their survey of recent metabolic research in this disease has led them to paraphrase this passage as follows :—

> "Whoever is acquainted with physiology and can render a man acidotic, dehydrated and fully oxygenated could also repress this disease, without minding purification of narcisistic personalities, ritualistic empirical diets and all other illiberal practices of a like kind."

Much interest has lately been focused, in America, on the possibility that the convulsions of epilepsy may be the expression of an underlying instability in water balance. It is certainly somewhat striking that several therapeutic measures which have been found to be of greater or less value in controlling convulsions—such as starvation, ketogenic diets, extreme limitation of fluid intake, and administration of acid-forming salts like ammonium chloride—have one effect in common, a depletion of the body fluids. Equally interesting is the work of I. McQuarrie,[2] who has been able to produce fits at will, in epileptic children, by increasing the intake of water and at the same time postponing diuresis by injections of pituitrin. These circumstances have led some writers to the conclusion that the epileptic convulsion is caused by an accumulation of cerebro-spinal fluid in the subarachnoid and perivascular spaces of the cerebral cortex. Temple Fay [3] believes that lesions of the Pacchionian bodies may be responsible, by interference with the egress of cerebro-spinal fluid. G. W. Swift [4] suggests that developmental abnormalities of the great venous sinuses may sometimes cause a similar obstruction, and has devised an operation for mobilising the lateral sinuses, which, he claims, decreases the obstruction, and, in selected cases, often relieves the convulsions. The anatomical vagaries of the veins draining the brain are so erratic, however, that it must be difficult to draw the line which separates the normal from the abnormal. Nor can this conception of epilepsy be satisfactorily reconciled with present knowledge. The subarachnoid spaces are admittedly often dilated in epilepsy, but it is hard to prove that this change is not the result of cerebral atrophy. Moreover, it is evident from elementary hydrodynamic principles that obstruction to the outflow of the cerebro-spinal fluid through the Pacchionian bodies must lead to a uniform rise of pressure throughout the ventricular system. Increased intracranial tension causes a very distinct clinical picture of headache, vomiting, papillœdema, and slowing of the pulse and respiration, and it is significant that the epileptic convulsion is preceded by none of these signs.

It is clear that the evidence does not support the interpretation outlined above. It does not follow, from the fact that *artificially* provoked dehydration may abolish, or water retention precipitate, fits, that the *spontaneous* convulsion is due to water retention. There is, in fact, no direct evidence that such is the case. And in this connexion some important observations, published by J. L. Gamble and B. Hamilton in 1927, which have been widely misinterpreted, deserve comment. These workers found that in epileptic children the excretion of water, sodium and chlorine increased during periods of convulsions and fell during the intervals between attacks—changes which indicated alternate release and retention of extracellular fluid by the tissues. Gamble and Hamilton themselves were intentionally non-committal about the import of these fluctuations, but subsequent writers have assumed that the retention of fluid before the convulsion constitutes the primary change, neglecting the more cautious alternative explanation—namely, that the convulsion itself causes a loss of body fluid, which is in turn succeeded by reactionary retention.

To exactly what extent disturbance of water balance enters into the ætiology of epilepsy must remain, for the present, unsettled. Meanwhile, to quote Lennox and Cobb, "The painstaking accumulation of apparently unrelated facts must go on until, like stones for a mosaic, they are sufficient in number to permit their assembly into a complete and intelligible design."

CRITICISM OF DIET.[5]

The Advisory Committee on Nutrition, in a recent memorandum to the Ministry of Health on the criticism and improvement of diets, have been admirably concrete in their recommendations. The members of the Committee are: Prof. Major Greenwood (Chairman), Dr. G. F. Buchan, Prof. E. P. Cathcart, Sir Frederick Gowland Hopkins, Miss Jessie Lindsay, Prof. E. Mellanby, and Prof. V. H. Mottram; a veritable array of exact informants. A diet to be satisfactory must fulfil four criteria: it must have an adequate caloric value and must contain a sufficient amount of first-class protein, mineral matter, and vitamins. The proper distribution of calories for a grown man is achieved if he takes 100 grammes of protein, 100 grammes of fat, and 400 grammes of carbohydrate per day. First-class protein, that is, protein with a high biological value, is found in cheese, eggs, fish. meat, and milk, and should be taken by a grown man to the amount of about 37 grammes, or 5 per cent. of the total caloric intake in the day. The Committee find that if a diet contains milk, and dairy produce generally, fish, eggs, vegetables and fresh salad (the "protective foods," protecting the body against deficiency diseases) there is little need to criticise it as regards mineral and vitamin content; and it is old experience that if the caloric, protein, and vitamin contents of the diet are adequate the carbohydrate can be left to take care of itself. Probably the mineral matter and vitamin content of the diet are satisfactory if made up as follows for one day and one person: 1 pint of milk; one orange, tomato, or helping of raw salad; one ounce of butter or vitaminised margarine; and, in addition weekly, especially in winter, some fat fish, such as herring; or, daily, half a teaspoonful of cod-liver oil. Defective diets in this country are usually the result of unscientific economy. Most institutions recognise certain foods which are cheap sources of calories, such as flour, oatmeal, bread, the pulses, dripping, margarine, treacle, sugar, and not far behind, butter, cheese, jam, bacon, and dried fruits. Cheese, herring, fish roe, and sprats are recommended by the Committee as economical sources of first-class protein, and need little cooking. Skimmed milk, if available, also provides first-class protein cheaply, and at the same time is valuable as a protective food. If margarine is to be given instead of butter, a brand should be used which can be shown to contain vitamins A and D. Diets are often found to be deficient in vegetables, both cooked and salad vegetables, particularly during the winter months, and the Committee point out that there is little excuse for this in England, where tomatoes, celery, lettuce, endive, and water-cress are easily and cheaply obtainable during the autumn and winter; a more general use of carrots, oranges, and lemons is also advisable.

[5] Report on Diets in Poor-law Children's Homes. Memorandum on the Criticism and Improvement of Diets. H.M. Stationery Office. *3d.* each.

In a report on diets in poor-law children's homes the Committee were able to show some of the ways in which institutional diets might fall short of their criteria. Much depends on the capabilities of the officers in charge of the homes; in certain of the scattered cottage homes a foster mother may be in almost sole control of about a dozen children, and is often directly responsible for the choice and purchase of food, as well as for cooking it. The cost of feeding these children is surprisingly low; in one case the allowance for food and cleaning materials for 12 boys and a foster-mother was £3 4*s*. a week, but it must be borne in mind that much of the food is bought at contract prices, so that the cash allowance has a greater value than it would if retail prices were paid. The Committee made the interesting observation that the cost of food per head in homes visited in the north of England exceeded that in homes visited in the south, despite the fact that prices in the north were on the whole lower than in London and the home counties. The additional cost was reflected in a better standard of feeding in the northern homes. The quantity of food supplied appeared to be sufficient, and there was reason to suppose that in general the children were better fed than they would have been in the ordinary homes of children of a like class. But the diets were open to criticism, usually under three heads: a desire to keep cooking down to a minimum; a lack of knowledge of food values; and a tendency to monotony. Three meals a day were served, breakfast from 7.30 to 8 A.M., dinner at 12.30 P.M., and tea at 5 to 5.30 P.M. In one home for children under 5 years of age breakfast was given at 7.30 A.M., dinner at 11.30 A.M., and tea at 3.30 P.M. We agree with the Committee in regarding this long interval between tea and the following breakfast as being most undesirable, more especially as their investigations show that both tea and breakfast were likely to consist only of bread, margarine, and cocoa.

Monotony was often the outcome of a fixed schedule of diet arranged to cover a week. The Committee advise that such schedules should be made to cover 8, 15, or 22 days, and provide an example of an eight-day schedule as an appendix. Dinner was the main meal of the day in all the homes and generally consisted of meat and two vegetables followed by a sweet. The usual constitutents of breakfast and tea have already been mentioned, but in some of the northern homes bacon was sometimes given for breakfast and tea was enlivened by tripe or stewed fruit. The Committee advise a redistribution of the food values over the three meals to avoid the concentration of most of the first-class protein, and probably most of the interest, in the mid-day meal. The supply of raw fruit was unsatisfactory, they found, and it seems more often to be regarded as a luxury than as a necessary part of the diet; cheese and cheese dishes are also subject to an unexplained neglect, and little use seems to be made of water-cress, even where abundant supplies are available. The existence of brands of margarine containing added vitamins does not seem to be generally known, and is certainly not sufficiently advertised by the makers. The Committee head their recommendations with the suggestion that a pint of milk daily should be allowed for each child and that special care should be taken to see that the full amount is received by every child under 16. They include a number of economical and nourishing recipes in an appendix which would repay study by all those responsible for institutional cookery on a large scale.

CRIME IN 1930.[1]

THE Criminal Statistics for the year 1930 present a somewhat depressing picture. Crime, it seems, is on the increase in England and Wales, and the ranks of the criminals are being recruited from among the youngest generation. The official commentaries on the Statistics for 1928 and 1929 had prepared us to expect a continuing addiction to lawless and adventurous crime on the part of the "war-juvenile" offenders who were deprived of full parental supervision 15 years ago. We might have guessed perhaps the effect of unrelieved unemployment upon the young, the stimulus of lurid cinematograph films, and the criminal possibilities which the mechanical bent of modern young people can find in the exploitation of the motor-car. Nevertheless, with the birth-rate falling and with the prolongation of life revealed by modern actuarial expectancies, it is startling to discover that two-thirds of all the persons found guilty of crime in 1930 were below 30 years of age, that two-fifths of the gross total were under 21, that only 7 per cent. of that total were over 50, and that even persons of the active ages from 30 to 50 constitute only 1 in 4 of the guilty. There is evidence that, in the face of this increase in crime, the courts in 1930 imposed more sentences and heavier sentences; but the young cannot be sent to prison till the full resources of the probation system and of Borstal Institutions have first been exhausted. Evidently the Probation of Offenders Act has been freely used, for, out of more than 11,000 boys found guilty, 89 per cent. were placed on probation. Offenders of both sexes and of all ages have had the benefit of the Act. The total of persons found guilty in 1930 was 56,767. No less than 28,365 of these (almost exactly half the total) were dealt with under the Probation of Offenders Act; of the remainder who had to receive some form of sentence, 13,762 were sent to prison, 532 to penal servitude, and about 750 to Borstal Institutions.

Official comments indicate that the increase in crime in 1930 lies mostly in offences against property. The position seems worst in the north of England where industrial depression has been severe. Small thefts have risen everywhere; "breakings-in" and kindred offences have risen too; violence against the person (other than sexual assaults) is rising; blackmail cases jumped to 94 from the previous year's figure of 49; and bigamy, after declining in the post-war years, is on the up-grade again. Two years ago the official editor of these Statistics remarked upon the relative constancy of the numbers of murders known to the police; it was then pointed out that, over a period of 60 years, the annual total had not fallen below 100 nor risen above 200. In 1929 there were 103 cases, excluding deaths of persons aged less than one year. In 1930 there were known to the police 75 cases of murder in respect of 86 persons aged one year or ove
Here, *therefore*, we *have* a notable decreas
The murderer or suspect committed suicide i
32 cases (involving 42 victims); in 35 cases 3
persons were arrested; in 8 cases no arrest wa
made. Of the 36 persons arrested 9 were acquitte
or were discharged at the police-court, 4 we
found insane on arraignment, 11 were foun
"guilty but insane," and 12 were convicte
6 of the 12 being hanged. Of the 8 cases in whic
no arrest was made, 3 of the victims had die
following illegal operations; these deaths pr
sumably increased the inevitable difficulty
obtaining evidence against a criminal abortionis
The tables show that 53 persons were charge
with the offence of procuring abortion (15 mal
and 38 females). Twelve were acquitted; t
remaining 41 persons were convicted, with t
result that 10 were sent to penal servitude a
22 to imprisonment, while 9 were released up
recognizances without a probation order. T
total of 53 persons charged compares with tot
of 43 for 1929 and 73 for 1928. The annu
average for the period from 1920 to 1924 w
32. Though the annual totals show a tenden
to rise, medical practitioners can form their o
opinion of the success of the police in bringi
this class of offender to justice. The year 19
shows an all-round decrease in the figures
coroners' inquests and investigations, as compar
with the previous year; no explanation is offe
of this phenomenon which certainly cannot
ascribed to diminished vigilance. In 7673 ca
there was a post-mortem examination with
inquest (a slightly greater number than in 192
the number of inquests with a jury rose in 1
to 12,999 from the 1929 level of 12,353. If
compare the totals of the kinds of verdicts retur
at inquests in these two years, we find a drop
cases of death due to want or exposure (fr
133 to 93), in deaths due to excessive drink
or drug-taking (from 172 to 141), and in dea
from disease aggravated by neglect on the p
of other persons (from 32 to 22). As usual
inquests on males are more than double those
females. There were 63 more suicides in 1
than in 1929; 41 fewer attempts at suicide w
brought to the notice of the police.

Those who study our Criminal Statistics regula
will regret that the chill penury of natio
economy has cut down the valuable introduct
comments which gave the volume great sociologi
interest in recent years. The Home Office, hav
access through its own specialists and thro
the Prison Commissioners to a mass of import
information, should make fully available to
the supplementary facts, explanations, and spec
tions which can enliven the arid and jejune colu
of tabular statistics. Two years ago we w
given 69 pages of official introduction, last y
only 32; this year we have a beggarly 21 pa
Recent events in penal institutions have stir
public attention. The next annual report of
Prison Commission must not be cut down in t
nip-farthing fashion.

ANNOTATIONS

THE FUNCTIONS OF THE TONSILS.

IN spite of much research, little is definitely known about the functions of the tonsils. L. B. Seiferth,[1] of Cologne, has recently reviewed at length modern knowledge of the subject, and a perusal of his essay emphasises the scantiness of this knowledge. He discusses the possible functions of the tonsils under the headings of lymphocyte formation, defensive function, and internal secretion, and he concludes that the only function which has been proved with certainty is the production of lymphocytes. This function the tonsils share with all the lymph glands of the body, and their extirpation cannot therefore, from this point of view, do much to alter the general bodily constitution. In addition there are good grounds for believing that the tonsils play an important part in the defensive mechanism of the body, and Seiferth believes that the involution of the tonsils at puberty may be connected with the fact that by this time a satisfactory degree of immunity has been achieved. Experiments directed to prove an internal secretion have so far been so contradictory as to be quite inconclusive. Seiferth holds that the theoretical problem can have at present but little influence on the practical one of clinical treatment, which may, in his opinion, be summed up in the two words "chronic tonsillitis"; but the diagnosis of this chronic tonsillitis, and therefore the indications for operation, have not so far been greatly influenced by physiological considerations. The practical side of the tonsil problem is dealt with very directly in a letter of instruction sent to school physicians by the Department of School Hygiene of the City of Boston[2] in the hope that such carefully formulated rules should tend to bring the school and family physicians into better accord. According to these rules the school physician should recommend tonsillectomy and adenoidectomy only :—

1. If the child gives a history of repeated attacks of acute tonsillitis or quinsy sore-throat ;
2. If the child has suffered from continuous head colds ;
3. If the cervical glands are definitely enlarged and have suffered from acute inflammation ;
4. If the child has obstructive nasal breathing (adenoids) ;
5. If the child has suffered from an attack of acute catarrhal or suppurative otitis media ;
6. If the child is a mouth breather ;
7. If the child gives a history of repeated attacks of pharyngitis, laryngitis, or bronchitis ;
8. If the tonsils obstruct the fauces, making the swallowing of food difficult ;
9. If the child gives a history of rheumatism, chorea, endocarditis, or nephritis ;
10. If there is evidence of a continuous discharge from the nose not caused by a sinusitis or antrum disease ;
11. If the tonsil is "buried" and therefore objectively not visible as a large structure but shows definite evidence of a diseased condition.

It does not, however, appear to follow that operation must be advised in all children falling into any of these groups. Nos. 4 and 6 seem to be synonymous, and it should be remembered that there are other causes of nasal obstruction in children ; No. 11 appears to beg the question, for removal may be advisable when a tonsil "shows definite evidence of a diseased condition" whether it is or is not buried. On the whole, these rules should achieve the purpose for which they have been framed ; but truly the "tonsil problem" is too difficult to be solved within so rigid a frame.

[2] New England Jour. of Med., March 17th, p. 592.

GLYCOSURIA AND PREGNANCY.

THE question of the significance of sugar in the urine should at all times be answered as accurately and quickly as possible so that the patient may be saved from unnecessary treatment on the one hand, or from delay in treating true diabetes on the other. In pregnancy this question arises frequently, because glycosuria without diabetes is a common concomitant of gestation. An annotation in our last issue indicated some of the dangers which have to be faced when true diabetes is present, and it is clearly of vital importance to have some ready means of distinguishing the two conditions. In the first place it is well to know how often simple glycosuria occurs in normal pregnancy, and Dr. L. A. Chase[1] has attempted to get this information. She obtained 100 specimens of urine from 18 patients in the latter part of pregnancy, and found sugar in 66 of these, while only two of the patients failed to show sugar on any occasion. Another woman carried out 100 examinations on her own urine, the tests being done four times a day for 25 days. Forty-seven of these specimens showed sugar, most often in the afternoon and rarely in the morning, but the fasting blood-sugar was normal. A further series of patients from private practice showed that glycosuria at some period after the second month is the rule in pregnancy, while in those patients in whom no glycosuria was found at any time it was easily induced by giving extra sugar in the diet. Sugar-tolerance curves were done in three cases, and curves similar to those found in renal glycosuria were found in all of these. After delivery the glycosuria disappeared quickly in all but three patients and sugar-tolerance tests done on these showed a renal leak. These have been examined at yearly intervals since, and have remained well during the last four years. Dr. Chase considers that glycosuria during pregnancy is normal and requires no treatment, and does not predispose to the development of diabetes. V. J. Harding and D. L. Selby,[2] in further discussion of the same subject, agree that its incidence is very high, and that it may be found in 100 per cent. of normal pregnancies if properly looked for. They hold that the factors which determine its presence are the diet of the patient, the volume of urine passed, and the time at which the specimen is passed in relation to the previous meal.

The common appearance of simple glycosuria during normal pregnancy may make the diagnosis of the rare cases of true diabetes very difficult for the practitioner. Clearly he cannot have complicated biochemical tests done on all patients who show a trace of sugar in the urine, but he must rely on some clinical criteria. There is certainly no single test or sign which will enable him to distinguish with certainty the two types, and the solution will depend, as in most other clinical problems, on a thorough survey of the history and findings in each individual case. Harding and Selby regard the following points as of most value in making the distinction. First, an absence of the history and symptoms of diabetes ; thirst, polyuria, and pruritus vulvæ are practically never found in so-called renal diabetes. Secondly, absence of sugar in the fasting urine, unless this is very concentrated ; if sugar is found a second fasting specimen should be examined after the patient has drunk eight ounces of water, and if sugar is again found, then the fasting blood-sugar should be determined, and this should be within the limits of normal if the glycosuria is physiological. Thirdly, an absence of ketonuria. To determine this they suggest a modification of the usual Rothera test, which is so sensitive that a positive finding in pregnancy is not significant. The Le Nobel[3] variation is less sensitive and a positive result is therefore of greater significance. Owing to the difficulty of distinguishing with certainty between glucose and lactose in the urine, Harding and Selby consider that it is safer to assume the presence of glucose when a reducing substance is found. If every case is approached on these broad lines the practitioner will find very few in which a sugar-tolerance test is necessary for diagnosis.

[2] Ibid., p. 283.

HIGH BLOOD PRESSURE AND RENAL DISEASE.

THE cause of the rise of blood pressure in chronic nephritis is far from clear. The view most commonly accepted is that the failure of renal function allows certain toxic pressor substances, which should normally be excreted in the urine, to remain in the circulation. The precise nature or origin of these pressor bodies is not understood, though they are thought to be nitrogenous and to be powerful vasoconstrictors. Another theory is that the actual tissue breakdown products of damaged kidneys act either directly upon the heart and blood-vessels, causing vascular spasm, or indirectly by stimulating the output of adrenalin from the suprarenal glands. A third suggestion is that the mechanical hindrance to the flow of blood through the kidneys, resulting from chronic nephritis, leads gradually to a compensatory increase of blood pressure required to maintain the renal circulation. A study of the degree of hypertension in various forms of renal disease throws some light on these mainly theoretical considerations, and M. Rosenberg[4] records some 20 cases that are of particular interest in this connexion. All the patients had died of actual uræmia with nitrogen retention in the blood, and they comprised cases of polycystic kidney, ascending pyelonephritis, hydro- or pyonephrosis, and renal tuberculosis. In other words they were cases in which there was extreme destruction of kidney tissue and a fatal renal insufficiency. In a large proportion of them, however, there was no increase in blood pressure, nor cardiac hypertrophy. Thus more than half of the 12 patients with ascending infection or urinary obstruction and hydronephrosis had a normal blood pressure with no ventricular hypertrophy; and in three fatal cases of polycystic kidney the same observation was made. It is thus again shown that there may be uræmia and complete renal failure without increase in blood pressure. Since the destruction of the kidney tissue may be extreme in these cases one must suppose that mechanical hindrance to the renal blood flow cannot at least be the sole cause of cardiovascular changes. Further, it seems improbable that mere failure of the kidneys to excrete pressor substances is enough to produce the increase in blood pressure. It is of course in chronic glomerulonephritis and arterio-sclerotic nephritis that hypertension is especially marked, and here the renal failure may be less extreme than in polycystic kidney. This suggests that there may be some qualitatively varying product of kidney cell destruction that causes vasoconstriction and high blood pressure, or even that some primary *non-renal* toxic substance causes both the vascular and kidney changes. This last appears to be the probable explanation in a number of cases, and also the pregnancy kidney, to take an example. Rosenberg concludes that since high blood pressure, with cardiac hypertrophy, is much rarer in the cases mentioned than in chronic glomerulonephritis or renal arterio-sclerosis, the increase of blood pressure is probably due to the presence of some chemical substance quantitatively if not qualitatively different in the different lesions.

INHERITANCE OF TEMPER.

WHILE it may be a true saying that no one can be a leader of men unless he can lose his temper, it is at least equally certain that many persons have no ambition to lead anything more exacting than a quiet life, and for this purpose an even temper is an asset. Dr. G. F. Still, writing in the *King's College Hospital Gazette* for February, mentions an investigation made by Francis Galton in 1887 to decide how far the possessor of a bad temper may lay the blame on his inheritance. Galton found that in 43 families in which both parents were good tempered, 30 per cent. of the children were good tempered, 10 per cent. bad tempered, and the remainder neutral, showing no marked tendency in either direction; in 25 families in which both parents were bad-tempered the number of good-tempered children was only 4 per cent., while bad-tempered children amounted to 52 per cent. As Dr. Still points out, the issue here is not simple, because the child living with bad-tempered parents is in an unfavourable environment from the start. He mentions other factors which may be detrimental to temper, such as indigestion and the exhaustion produced by a long illness. The possibility that endocrine imbalance has a bearing on temper cannot be overlooked; irritability is a common accompaniment of puberty and the menopause, and Dr. Still refers to the comfortable temper of the cretin and the myxœdema patient, and to the improvement sometimes observed in the temper of a thin child who begins to fatten.

But he concludes that we start life handicapped or blessed by a lower or higher coefficient of irritability; "we all have our flash point of anger or irritation," he says, "but in some the flash point of irritation is lower than the average." And though he grants that some, with tactful training, may acquire an artificial repression of impulses which makes a negative substitute for good temper, for those to whom ill-temper belongs by heritage and environment he has sympathy but little hope. He takes, perhaps, rather a dark view of the case. While it is true that there is a type of temperament which can be happy in any circumstances, there is another type which can be happy in some circumstances and not in others. Most of us have encountered men who were cheerful while their affairs were in good train but who became irritable and whining in the face of disaster; the cantankerous wife of an unsuccessful husband may be transformed into a delightful person by the removal of financial anxiety. Children, it has often been observed, may behave charmingly at school and yet like a generation of vipers at home. There is, moreover, a possibility that the legend of a "family temper" may become a fetish which has to be satisfied with unwilling victims. This may explain the case of a boy who constantly indulged in violent temper tantrums—"just as your uncle George used to do," he was told. His parents were sympathetic, but he made no attempt to master his rages, as they had a sound hereditary reason. But his temper in manhood was unusually equable, and a friend, father of an irritable son, asked him how he had been stimulated to make this conquest. "It wasn't a conquest," he replied. "I grew out of it, or rather it grew out of me. I know it used to infuriate me when my parents moaned about the family temper, and I used to give them something to complain about." In fact he made not the slightest attempt to control his temper at home, but abroad he learnt the need of restraint.

---

[3] To 6–10 c.cm. urine add two small crystals of sodium nitroprusside. Dissolve. Add 2 c.cm. of glacial acetic acid. Mix and freely overlay with concentrated aqueous ammonia. A purple or permanganate colour develops where the liquids are mixed.

[4] Deut. med. Woch., 1932, lviii., 206.

Although inheritance may play an important part where either good temper or bad temper is a marked characteristic of the children, a large number of people belong to the neutral group of Galton's investigation; the temper of these, it seems fair to suppose, will be made or marred by circumstance, though the bias need not necessarily be permanent in either direction. Dr. Still draws attention to the intrinsic truth of the phrases "tired and cross," "fat and jolly," and to these we may perhaps add another tag to the effect that "it's easy to be pleasant when things are going right." This was doubtless invented by a neutral-tempered person during a disgruntled phase, and probably has as sound a basis of experience as the other two. The subject might repay further research; or it might not.

ABDOMINAL SYMPATHECTOMY FOR HIRSCHSPRUNG'S DISEASE.

At a meeting of the Section for the Study of Disease in Children of the Royal Society of Medicine, held on April 1st, Mr. L. E. Barrington-Ward read a short communication on excision of certain portions of the sympathetic nervous system within the abdomen for the relief of Hirschsprung's disease. He based his remarks on three cases recently treated in this way and as an illustration demonstrated a film showing exactly the operative procedures employed. This indicated very clearly the excision of the two presacral nerves from behind the posterior layer of peritoneum in association with certain nerve plexuses lying over the promontory of the sacrum. Sympathetic nerve-fibres were removed as high up as the origin of the inferior mesenteric artery from the abdominal aorta. As only a short time had elapsed since the carrying out of this procedure in his three cases Mr. Barrington-Ward was guarded in his remarks as to the possibility of cure, but a striking feature of each case was the immediate return after operation of the ability to pass a normal daily motion without the use of purgatives. At the same meeting Dr. J. H. Gibbens demonstrated a little girl in whom a similar operation had completely failed to give any relief and it is obvious that not every case of dilated colon is suitable for this remedy. This is well brought out in a recent paper in which E. W. Rankin and J. R. Learmonth[1] review the present position, especially as regards the modified operative procedures introduced by themselves. They discuss the ætiology of megacolon under five headings: true congenital defects, such as cause Hirschsprung's or Mya's disease, obstructive processes, anatomical factors, infective processes, and neurogenic processes. While it is usually accepted that there is no gross obstructive or faulty nervous mechanism in the congenital group of cases, Rankin and Learmonth hold that the pathogenesis is often a mixed one where various factors, outlined above, may come into play. Nevertheless in the congenital cases the deciding ætiological factor seems to be a neurogenic abnormality; but the subsequent pathological changes differ in no essential from those produced in a dilated colon due, for example, to a constricting carcinoma. This may possibly explain the reason for failure in Dr. Gibbens's patient, for such secondary change may become too advanced for nerve section to prove effective. The lower part of the large bowel receives a dual innervation from the parasympathetic and sympathetic fibres. Sympathetic fibres can be shown by experiments on dogs to carry impulses which lead to dilatation of the colon and contraction of the internal sphincter of the rectum. These fibres come in part from the large ganglia in the upper part of the abdomen, descending on the aorta to the origin of the inferior mesenteric artery, and in part from the mesially directed branches of the four lumbar sympathetic ganglia on each side. From the network of nerves round the root of the inferior mesenteric artery, two large strands become separated and pass out along the trunk of the vessel, while the remainder passes downwards as the presacral nerve or nerves to join the hypogastric ganglia. The operation devised by Rankin and Learmonth consists in resection of this presacral trunk which is followed upwards to the root of the inferior mesenteric artery and the nerves passing out along this artery are then divided. This operation appears to be the one adopted by Mr. Barrington-Ward and illustrated in his film. Rankin and Learmonth in the present paper report eight cases with successful results. The patients varied in age from 2 to 28 years. In some cases the operation on the sympathetic nervous system had been performed as long ago as 1927, so that good opportunity for seeing the actual results of the proceedings was afforded. These results seemed to have been uniformly good and taken in conjunction with Mr. Barrington-Ward's efforts in this country the future treatment of Hirschsprung's disease by what is essentially a simple procedure, as compared, for example, with excision of the colon, should be full of hope.

THE NEWER MATERIA MEDICA.

The three main ideas which have revolutionised medical science since the middle of last century are those of the infective cause of disease, internal secretion, and accessory food factors. As a consequence, therapeutic interest has shifted to some extent from the older drugs of the pharmacopœia to sera and vaccines, hormones, and vitamins, and these now constitute an important part of the modern materia medica. While it is possible to disagree with Dr. Burn's view[1] that insufficient attention is paid to them in the teaching of pharmacology to medical students, everyone will concur in his statement that the newer knowledge finds almost no place at all in the teaching of pharmacists. To remedy the defect, he gave a course of lectures to members of the Pharmaceutical Society in London, and these lectures are the basis of his new book. The reader must not expect, therefore, to find a discussion of all the recent advances in materia medica, but he will enjoy a lucid account of those made in the field which is being most actively cultivated at the present time. The book is intended primarily for pharmacists, but the medical student and practitioner will find in it much information difficult to obtain in any other single volume. He will read of the methods of preparation and of the principles which underlie the action of antitoxins and vaccines; he will find a well-balanced account of the action and uses of the internal secretions, including those of the sexual glands and the anterior lobe of the pituitary; and he will learn something of the great expansion of knowledge of accessory food factors.

CLIMATE, DISEASE, AND FERTILITY.

THE enervating effect of tropical climates on people from temperate zones is well known, and Dr. C. A. Mills[1] thinks their condition is due to the monotony of unchanging good weather. Activity and achievement may thus be less a question of racial character than of fluctuations of climate, and he has set out to inquire whether there is evidence that a bracing climate may over-stimulate certain members of the population to the point of breakdown. As indications of the incidence of such breakdown he has taken the death-rates from exophthalmic goitre, pernicious anæmia, and diabetes, which he classifies as exhaustive diseases. This is to assume a great deal at the outset. The ætiology of these diseases is obscure, and there is no strong case for regarding them as being due to exhaustion rather than to any other cause. The suicide-rate, which he has taken as an indication of the incidence of mental failure, seems to be a less equivocal criterion, though it is hard to believe that climate is the only, or even the chief, factor affecting it. He is able, however, to show a definite correlation between the death-rates from these four causes and temperature fluctuations in different regions of North America. Storms appear for the most part in the north-west of the continent and sweep across the central States, and finally east across New England. Storm frequency is greatest from the Great Lakes area eastward up the St. Lawrence River, but much wider ranges of temperature accompany the storms near their point of origin in the north-west, while from the Great Lakes eastward the temperature changes diminish in amplitude. It is found that the death-rate from diabetes is highest in the west central States and follows quite closely the temperature variability, while the death-rate from exophthalmic goitre shows an even closer correlation with temperature fluctuations, and the distribution of deaths due to pernicious anæmia is much the same.

Dr. Mills goes on to say that a similar geographical difference in severity is associated with leukæmia, heart disease, arterio-sclerosis, angina pectoris, and chronic nephritis, which he classifies as not due to infection—another unproved assumption. He finds that the southern States show a low death-rate from these diseases, and that the area of greatest severity nearly always coincides with the maximum temperature variability. His argument is strengthened by the fact that the total death-rate is lowest where the death-rate from metabolic diseases is highest. The suicide-rate also appears to follow the greatest fluctuations in temperature, except in Florida and the Pacific coast; here the suicide-rate and the death-rates from metabolic diseases are high though this region shows neither high storm frequency nor high temperature variability. At this point Dr. Mills deserts his argument for a fresh one; he quotes the work of Ellsworth Huntingdon and himself to show that human efficiency and productivity are highest in areas where the mean temperature is near 64° F., a condition which applies to the Pacific coast, and ascribes the high incidence of metabolic diseases and the high suicide-rate in this region to a climatic drive applied throughout the entire year with no depressive periods to counterbalance it. Though the correspondence between variability of climate and the death-rates from the causes indicated is suggestive it seems scarcely justifiable to draw any decided conclusions from it. There might be a dozen factors besides climate which could be shown to vary to some extent with the incidence of the diseases chosen, and to regard any one as the responsible factor without further evidence is rather like saying that because cancer and the consumption of tomatoes are both on the increase, tomatoes must be the cause of cancer.

A second investigation[2] by Dr. Mills into the relation between sexual activity and climate is, perhaps, less open to criticism. He finds that the peak of fertility in married women in America is occurring at earlier and earlier ages, and that there is a progressive decline in fertility after 30 years of age; in the south fertility is initially less, but is more sustained, than in the north, and results in greater total productivity. He has also collected evidence to show that a change to an earlier age of onset of menstruation is taking place, and that this change is progressing more rapidly in the northern area of high storm frequency than in the south. He draws attention to the important social applications of these facts: with the peak of fertility and sexual activity coming earlier and the age at the time of marriage changing in the opposite direction, birth control will soon be unnecessary to curb over-population. At the same time the social and sexual problems of unmarried girls are being intensified, and he commends this to the recognition of workers in the social sciences.

FASCIAL PLANES.

FOR some years there has been a tendency among English anatomists to lay less stress on the various layers of fascia which their precursors dignified with elaborate description and many names. They are inclined rather to look on such layers as actually non-existent and to consider the several muscles and vessels and nerves as lying in a bed of areolar tissue, which only falls into layers round them when cut into by a knife. This does not apply, of course, to those true strata which contain a basis of aponeurotic fibres. The practical value of fascial layers remains, for it matters little if the division is made by a knife or by a purulent or hæmorrhagic effusion, and the surgeon is always preceded by a knife in the locality under investigation of these planes. This conception of fascia, however, admits of many descriptions, differing, but of equal value, because the result attained by the dissector will vary in detail according to the methods or preconceptions of any particular worker. Dr. B. B. Gallaudet, of Columbia University, has brought out a small book on fascial planes particularly in the abdomen, pelvis, and perineum.[3] He has studied the fascia in some 34 bodies during the last 17 years. He gives detailed accounts, which differ in many ways from the usually accepted ideas, but in spite of his patient research seem to us to exemplify only another and more complicated variety of the personal descriptions which our conception of fasciæ invite. Readers may find the descriptions difficult to follow, but those whose work lies largely in relation with the pelvic floor may be encouraged to make the attempt; they will at any rate see that there are more ways than one of looking at any object of interest.

[3] A Description of the Planes of Fascia of the Human Body. By B. B. Gallaudet, Department of Anatomy, Columbia University, New York. Columbia University Press and Humphrey Milford, Oxford University Press. 1931. Pp. 75. 14s.

A paper by Dr. J. W. Davies,[4] dealing with the surgical applications of fascial arrangements in the abdomen and pelvis, provides some illustration of what has been said. There is nothing that is not true in this author's ideas, save the idea itself, and the same may be said about the notions of Mundinus and of a multitude of writers since. The idea, to our mind, is wrong because it is artificial. Schematic renderings and analogies, useful enough for aiding comprehension, do not constitute anatomy. It would seem to us to be a truer description of the connexion of the vagina, for example, to talk of this organ as lying in the well-developed pelvic subperitoneal areolar bed, and thus connected with the levator—and, by the way, the vagina is in direct relation with the levator laterally as far as the fornix. Areolar tissue is always thickened round vessels, and the vagina presents no exception in this way. We could have no particular objection to the plan, as a plan of arrangement, advanced by Dr. Davies, but we cannot help feeling that a better notion of actual conditions can be obtained by adopting an anatomical outlook based on the ideas mentioned above.

AMBLYOPIA OR FATIGUE?

In Dr. Stutterheim's paper on p. 774 of this issue amblyopia is defined as "partial loss of sight devoid of ophthalmoscopic or other marked objective signs," and he claims to have cured many cases of amblyopia associated with weak converging power by treatment by means of prisms calculated to increase the power of the converging muscles. The claim is novel and before admitting it, it may be well to examine the term "amblyopia" more closely. Toxic amblyopia may conform to the above definition but depends on well-known definite causes which point to the necessary treatment. Amblyopia ex anopsia applies, as a rule, to a squinting eye in which although the retinal apparatus may be perfect the power to interpret the retinal image has never been properly developed. It also applies to some cases of congenital cataract in which operation is deferred until after the age at which the power of interpreting the retinal image is normally acquired. Now it is well known that with equally perfect retinal apparatus the power of interpreting the retinal image varies greatly in individuals. The countryman can see many things in the landscape that entirely escape the observation of the visitor from town. The student can read fluently what the hand worker will stumble over, and it is seldom that small children who have recently acquired the art of reading can make out the bottom line of the distant test type, even though their refraction is normal. The difference is not in visual acuity, but in power of interpretation. Even in the same individual this power may and does vary from time to time, and the same conditions which cause weakness of convergence in anyone who is run down in general health are also liable to affect his mental alertness so that at one time he may be able to read 6/6 with ease and at another time not. We would suggest to Dr. Stutterheim that the term amblyopia is hardly a suitable one for a psychical condition that affects both eyes, and that any measures that produce an amelioration of this condition are effective not so much through the muscles as the mind. Mental fatigue may cause weakness of convergence, and any measures successful in curing weakness of convergence may react favourably on mental fatigue.

PAPULAR URTICARIA.

Dr. Rupert Hallam's original observation that hospitalisation in itself is usually sufficient to cause a temporary clearance of papular urticaria (lichen urticatus) has been confirmed by other workers. Since he recorded this interesting fact, four years ago, he has discovered that he can get the same result if the affected children are detained for the nights only, and he now records[1] 11 cases in which no new lesions appeared so long as the patient slept at hospital. The cause therefore appears to have been narrowed down to something which operates during the nights under home conditions. Experiments with bedding, and the like, which was transferred to the hospital, were negative. A similar peculiarity of apparent reaction to home environment has long been known in the case of a much more serious disease—Hebra's prurigo. In this condition the extensor surfaces are covered with intensely irritable papules, and there is usually enlargement of the inguinal and axillary glands. Even in its most severe forms (prurigo ferox, limited to boys and young men) simple hospitalisation has often initiated a clearance, if not a cure. In his summary Dr. Hallam concludes that papular urticaria is an allergic manifestation to an undiscovered antigen which is not a food factor but is probably associated with the home sleeping arrangements. The disease is relatively common, accounting for 20 per cent. of all cases in some years in the skin departments at the Great Ormond-street and East London Hospitals for Children. The actual cause is therefore of considerable importance, and every dermatologist appreciates Dr. Hallam's careful work and observation and will wish him eventual success.

THE REVOLUTION IN SANATORIUM TREATMENT.

At the beginning of the century sanatorium treatment was distinguished by its elemental simplicity. Plenty of fresh air, of food, of rest—that was all. The successes achieved proved how much we starve ourselves of these elementary requisites under modern conditions. It was, however, difficult to be complacent over these results, for no satisfactory reply could be found to the criticism that many of the patients cured by sanatorium treatment would have recovered without it, and that the sanatorium did little or nothing permanent for patients in the second and third stages of tuberculosis. This criticism is, indeed, so pertinent that it might by now have greatly discredited sanatorium treatment as a whole had not the Forlanini revolution intervened. It is necessary only to compare the sanatorium reports 30 years ago with those of to-day to gauge the extent and effects of this revolution. The report for 1931 of the late Prof. Saugman's sanatorium at Vejlefjord in Denmark shows how variedly surgical the treatment of pulmonary tuberculosis has become. In this year there were discharged 138 patients who had suffered made in the field which is being most actively cultivated at the present time. The book is intended primarily for pharmacists, but the medical student and practitioner will find in it much information difficult to obtain in any other single volume. He will read of the methods of preparation and of the principles which underlie the action of antitoxins and vaccines; he will find a well-balanced account of the action and uses of the internal secretions, including those of the sexual glands and the anterior lobe of the pituitary; and he will learn something of the great expansion of knowledge of accessory food factors.

THE REVOLUTION IN SANATORIUM TREATMENT.

At the beginning of the century sanatorium treatment was distinguished by its elemental simplicity. Plenty of fresh air, of food, of rest—that was all. The successes achieved proved how much we starve ourselves of these elementary requisites under modern conditions. It was, however, difficult to be complacent over these results, for no satisfactory reply could be found to the criticism that many of the patients cured by sanatorium treatment would have recovered without it, and that the sanatorium did little or nothing permanent for patients in the second and third stages of tuberculosis. This criticism is, indeed, so pertinent that it might by now have greatly discredited sanatorium treatment as a whole had not the Forlanini revolution intervened. It is necessary only to compare the sanatorium reports 30 years ago with those of to-day to gauge the extent and effects of this revolution. The report for 1931 of the late Prof. Saugman's sanatorium at Vejlefjord in Denmark shows how variedly surgical the treatment of pulmonary tuberculosis has become. In this year there were discharged 138 patients who had suffered from active pulmonary tuberculosis. Only 13 were in the first stage of the disease; as many as 88 were in the third stage. Yet, 119 of these patients were discharged cured or improved. Of 104 sputum-positive patients as many as 42 became consistently sputum-negative. Of the 60 who were febrile on admission, 43 were discharged as afebrile. As many as 27 suffered from tuberculosis of the larynx as well as of the lungs. The list of surgical interventions is impressive, not only by virtue of numbers, but also of variety. As many as 69 out of the 138 patients were selected for pneumothorax treatment, which, however, did not prove feasible in 29 cases because of pleural adhesions. Phrenico-exairesis was performed in 25 cases, total thoracoplasty in 6, partial thoracoplasty in 30, supplementary thoracoplasty in 2, simple thoracoscopy in 3, thoracoscopy with cauterisation of adhesions in 13, simple thoracocentesis in 4, thoracocentesis with air substitution or pleural irrigation in 21, Bühlow's drainage in 3, oleothorax in 9, and galvano-cauterisation in 36 cases. Sanocrysin was given to 43 patients, universal carbon arc light treatment to 46, this treatment being supplemented by local quartz light treatment in 5 other cases. About 25 patients enjoyed sun- and sea-bathing in the summer. Only 31·8 per cent. of all the sputum-positive patients treated during the 31 years of the sanatorium's life became sputum-negative, whereas in 1931 40·4 per cent. of the sputum-positive patients achieved this result. Judged by various other criteria, the results of sanatorium treatment at Vejlefjord were much better in 1931 than in the aggregate; and this result is the more striking because the diagnosis of pulmonary tuberculosis is nowadays made to depend on very definite signs.

It is encouraging to find Prof. Saugman's successor, Dr. J. Gravesen, continuing to set the pace in the sanatorium world.

THE HÆMOPOIETIC FACTOR IN GASTRIC JUICE.

WE commented last week upon the growing importance of gastric physiology to hæmatology. Dr. J. F. Wilkinson and Mr. Louis Klein, Ph.D., in the same issue described a method for extracting a hæmopoietic factor from stomach which appeared to differ from that found in liver and which they suggested should be called "hæmopoietin." A preliminary report from a group of workers in Cincinnati now adds further to our knowledge of the part played by gastric secretion. Morris and his associates[1] have found that normal gastric juice, after neutralisation, can be given by intramuscular injection to both animals and man without any serious reaction. A negligible reticulocyte response followed the injection of 10–20 c.cm. of such juice, but after concentration by vacuum distillation at a temperature below 40° C. a highly potent product was obtained. Ten hours after the first injection of a concentrate from 450 c.cm. of normal gastric juice there was a reticulocyte response up to 5 per cent., and 36 hours after, a level of 17·6 per cent. was reached, the initial red cell count being 2,100,000 per c.mm., which suggests that the material was of satisfactory potency. "Addisin," after Thomas Addison, is proposed as the name for this effective factor which it is suggested is probably an internal secretion of the stomach. This would account for the poor results obtained by administering gastric juice by mouth. Gänsslen[2] and Wilkinson and Klein have also reported satisfactory results from the parenteral administration of stomach preparations. The relationship or possible identity of hæmopoietin, addisin, and Castle's intrinsic factor remains undetermined.

CURABILITY OF CANCER OF THE STOMACH.

Dr. E. B. Benedict has produced a paper[1] which may usefully be read in conjunction with those of D. C. Balfour and others reviewed in our annotation of March 26th. He describes a group of 29 cases of gastrectomy, in only eight of which the patient survived operation by a year or more. The average duration of symptoms was nine months, but in six of the eight surviving cases the history covered less than five months. In view of the importance of early diagnosis, Benedict, too, emphasises the necessity of early gastro-intestinal radiography. The operative mortality is high, 48 per cent. of the patients dying within a month. In studying the pathology large longitudinal sections were made, and 290 lymph glands were examined. Benedict does not agree with Balfour about the value of the grading of the tumours in prognosis, and has abandoned it because of the difference in types of tumour encountered and the structural variation of different parts of the same tumour; he further describes three cases in which the clinical results would not bear out the histological findings if grading were attempted. The lymph glands were involved in 17 cases as follows: subpyloric, 11; lesser curve, 10; greater curve, 6; retropyloric, 5; and cœliac, 3. Of the eight cases which survived 12 months or more, in six the lymphatic glands were found to be not involved. The size and macroscopic appearance of the glands cannot be relied on to indicate malignant involvement

JEFFERY MARSTON.

THE interesting account of undulant fever which appears in this issue of THE LANCET from the pen of Sir W. Dalrymple-Champneys opens with a reference to the late Surgeon-General Marston's recognition that "Malta fever," as it was then called, was a clinical entity. There are old readers of THE LANCET who may still recollect the distinguished officer in question. Marston was for many years our adviser on medico-military subjects, and was qualified in a very complete manner to give us that assistance. As a young man he had been secretary to the P.M.O. in India; he prepared the schedule of field organisation for the Afghan War 1877; in 1882 he was sanitary officer to the Egyptian Expedition; and he was later head of the statistical and sanitary branches of the Army Medical Board. In 1888 he was P.M.O. of the British Forces in Egypt and was responsible for the medical arrangements at Suakim, and on his retirement from the Service he was appointed president of the Army Sanitary Commission and a member of the Indian Medical Board. His retirement from active service coincided with the breakdown in health of James Wakley, the second editor of THE LANCET, and it was to Marston, in particular association with the late Dr. James Grey Glover, that James Wakley turned for assistance in the conduct of this journal for a long period.

WE regret to announce the death in his forty-fifth year of Dr. Alexander Lewis Urquhart, professor of pathology in the Egyptian University, which occurred on March 28th in Cairo.

SPECIAL ARTICLES

UNDULANT FEVER.

A CLINICAL REVIEW.*

BY SIR WELDON DALRYMPLE-CHAMPNEYS, BT., M.D., M.R.C.P.,
A MEDICAL OFFICER OF THE MINISTRY OF HEALTH.

THE identification of undulant fever as a clinical entity is due to Marston who, in the Army Medical Report for 1861 (published in 1863), sorted out, with remarkable clinical acumen, from the rubbish-heap of the continued fevers of the Mediterranean area, a disease which he named "Mediterranean or gastric remittent fever."

In 1886 the causative organism was discovered by Sir David Bruce, and was named by him the *Micrococcus melitensis.* It has since been renamed the *Brucella melitensis* in honour of its discoverer, the brucellæ being now recognised as a separate genus, of which *melitensis, paramelitensis, abortus, para-abortus,* &c., constitute species or more likely varieties or strains of a single species. In 1897 Hughes published a classical monograph on the disease which gives a clinical picture of the Mediterranean type which has never since been equalled. We come next to the famous British Commission on Mediterranean Fever formed under the auspices of the Royal Society in 1904 with the coöperation of the War Office, the Admiralty, and the Civil Government of Malta, and with Colonel (afterwards Sir David) Bruce as chairman. On June 14th, 1905, Dr. Zammit, a member of the Commission, found that the blood-serum of five out of his six experimental goats (which had *not* been artificially infected) agglutinated the *Micrococcus melitensis,* and a week later Major (now Sir William) Horrocks found the organism in large numbers in the milk of a naturally infected goat. That this was the chief source of undulant fever among the forces of the Crown in the Mediterranean was soon proved by the virtual suppression of the disease among these men following an order forbidding the consumption of unboiled goat's milk.

The next event to which I would draw attention was the discovery by Kennedy in 1914 of the presence of agglutinins for *Micrococcus melitensis* in the milk and blood-serum of cows in London, an observation confirmed by other workers but for long lost sight of owing to the war. In 1918 fresh light was thrown on Kennedy's observations by Alice Evans in America, who made the illuminating discovery that the *M. melitensis* was very closely related to the *Bacillus abortus,* shown by Bang in 1897 to be the cause of contagious abortion in cattle. From this time onward progress has been rapid, and cases of undulant fever due to one or other member of the genus brucella and confirmed by positive blood cultures, or more often only by agglutination tests, have been reported from all over the world, not excluding this country. In most of the cases occurring elsewhere than in the Mediterranean area the infection has been acquired from cattle chiefly through their milk.

UNDULANT FEVER IN ENGLAND AND WALES.

When I wrote my report on this disease for the Ministry of Health in 1929, only 14 cases of endemic origin (excluding laboratory infections) had been reported in this country. Since then accounts have been published of 14 other cases in England and Wales and 3 in Scotland, and I have received details of 18 additional cases in England and Wales and 1 in Scotland, most of which I have seen, in which the diagnosis was, in my opinion, certain, but accounts of which have not so far been published. This total of 50 cases is, of course, a small one, but I am more than ever inclined to the belief, which I expressed in 1929, that a considerable number of undiagnosed cases occur each year in this country. The experiences of Denmark will perhaps suffice to illustrate the reasonableness of my apprehensions.

Before April, 1927, the presence of human undulant fever in Denmark was quite unsuspected, though contagious abortion in cattle was known to be widespread, as it is in this country. By Dec. 1st, 1928, as the result of the routine testing of Widal bloods for brucella agglutinins in the State Serum Institute at Copenhagen, 500 cases had been discovered, each with an agglutination titre for *B. abortus* of at least 1 : 100, and with the clinical characters of undulant fever. Fresh cases have been reported from Denmark at a corresponding pace ever since, and the United States, Canada, Sweden, Poland, Switzerland, Germany, Holland, and other countries have made similar discoveries though only the United States has experienced an incidence as heavy as that of Denmark.

Kristensen's comment on his Danish cases is worthy of serious attention. He says :—

> "As the presence of abortus bacillus infection among human beings was quite unknown in this country until these examinations took place, there is no reason to suppose that this infection has been especially frequent within the last few months. What has happened is that some of the feverish infections which previously had either not been diagnosed or wrongly diagnosed, were now correctly diagnosed. There is no reason to believe that this infection is more widespread here in Denmark than in countries where cattle breeding is carried on to the same extent; it must be supposed that if systematic enquiries of a similar nature were set on foot in Germany and in England the same conditions would be found."

In Germany such inquiries have been carried out since then (though in that country serological work is not centralised to the same extent as in Denmark), with the result that between Oct. 1st, 1929, and August 30th, 1930, 626 human cases of *Br. abortus* infection were diagnosed. In this country a slowly increasing interest is being taken in the disease, but systematic investigations on a large scale have not been carried out, and I find in my travels over the country that only a small proportion of our profession is alive to the possibility of brucella infections among their patients, and that even in pathological laboratories the examination of Widal bloods for agglutinins for this group is quite infrequent.

CLINICAL.

A great deal has been said and written about the clinical differences between undulant fever of the Mediterranean type, due to infection with the *Br. melitensis,* and the type which is now much more common and widespread, and which is due to the *Br. abortus.* However, the more I read the old descriptions and the more cases I read about or see, the less value do I attach to these distinctions. In illustration of my point I may quote the beginning of Marston's original description of "Mediterranean or Gastric Remittent Fever."

---

* Abridged from a paper read before the Paget Club, St. Bartholomew's Hospital.

He says :—

> "By this is meant a fever characterised by the following symptoms and course: A preliminary stage of subacute dyspepsia, anorexia, nausea, headache, feeling of weakness, lassitude, and inaptitude for exertion, mental or physical, chills, muscular pains; lastly, a fever, having a very long course—three to five or ten weeks—marked by irregular exacerbations and remissions, great derangement of the assimilative organs, tenderness in epigastric region, splenic enlargement, slight jaundice without any exanthem. Neither bronchitis nor diarrhœa as a rule. The patient is prone to relapses and the disorder is followed by a protracted convalescence and a chloro-anæmic aspect. . . . There is no fever so irregular as this in its course and symptoms."

The last sentence is particularly noteworthy. The great irregularity will often suggest the diagnosis and, if borne in mind, will often save us from a rash prognosis.

The above word-picture of undulant fever was drawn by the master hand of one who alone had the vision to distinguish in the fog of the remittent fevers the clear-cut features of this formidable enemy of mankind.

From this point I shall speak of the disease chiefly as occurring in this country. Undulant fever is commoner in males than in females (of the cases in Great Britain 33 were males and 11 females), and most often attacks those between the ages of 15 and 45. It is very uncommon in children under 5 years, but the English cases include a boy of 3½ years and an infant of 20 months. The incubation period is probably from 3 to 14 days, but the usually gradual onset makes it very difficult to determine. Though the onset is usually gradual, this preliminary stage may be terminated by a sudden and considerable rise of temperature with an exacerbation of symptoms. Cases with a *really* sudden onset, without any preliminary stage, are very rare, but the type of case in which no abrupt transition occurs is comparatively common, and in these there is sometimes discernible a gradual increase of severity to a maximum followed by a gradual amelioration of symptoms. The "great derangement of the assimilative organs" described by Marston has hardly ever been observed in this country, but anorexia is nearly always present. On the other hand, bronchitis, which was very uncommon in the Mediterranean, is not infrequently present here, though in a mild degree, sputum being almost always absent and definite physical signs in the chest being difficult to detect.

The most striking feature of the disease is the behaviour of the temperature. In spite of the extraordinary variations observed in different cases and in any one case, there is something about these temperature charts which experience enables one to detect as being characteristic of this disease.

For the sake of clearness I propose to divide the temperature charts into three types, but it should be clearly understood that often all types are seen at different stages of the same case, and few charts are quite characteristic of their type throughout the course of the disease. The first and most frequent type of chart usually begins "in the air," that is to say, at the time when the temperature is first taken it is found to be anywhere between 100° and 106° F., though the history makes it probable that the temperature has been raised for some days or weeks before this. In this type, first described by Hughes, and the frequency of which made him suggest the name of "undulant fever" for the disease, the temperature chart shows a number of waves, lasting usually for about a week, and connected by comparatively flat troughs which are often situated some way above the normal line.

The waves are not constituted by a simple
but are composed of a number of zigzags,
usually representing one day's record. And
brings me to the two most characteristic featur
these charts, which are seldom absent throug
the course of a case of any type—namely, (1
afternoon or evening rise, followed by a fall i
night or early morning; and (2) the sudden
swings, a drop of 4° or 5° in an hour being
at all uncommon. I must here mention an impo
symptom which is not included in Marston's des
tion of the disease, but which he does not fail to
elsewhere—namely, the heavy sweats which us
accompany these sudden falls of temperature. T
sweats are often literally "drenching," and somet
(though not as often apparently as in the Mediterra
region) they have a peculiar sour smell, which
characteristic that a physician well acquainted
the disease will detect a case in his ward the mo
he enters it. Relapses are common in this va
of the disease.

To return to the temperature charts, the se
type, called by Hughes the intermittent type, s
a less intense but more hectic fever with less tend
to relapses and fewer and milder symptoms.

The third type of chart is the completely irre
and this may be found in the mildest or most s
cases of the disease. In this type the tempera
wanders along with rises or falls at irregular inte
and of irregular duration, the temperature somet
rising swiftly to a peak, from which it may des
with much greater caution, or suddenly plun
into an abyss only to rise as suddenly a few h
later to its former level. These wild excur
break the monotony of an extensive platea
interrupt unexpectedly the even level of a pea
plain. In spite of this tendency to extreme ir
larity these charts seldom fail to display at some
in their course the evening rises followed by mor
falls which are so characteristic.

One phenomenon which cannot fail to strike
observer is the extraordinary discrepancy bet
the height of the temperature and the general
dition of the patient. In no other disease
which I am acquainted does the patient emerge
a prolonged and severe struggle against fever
so few evidences of the battle detectable.
anomaly constitutes in some cases a valuable a
diagnosis.

I may here mention that the occurrence of abor
in women due to infection with an organism of
brucella group is now proved, and the causa
organism has been recovered in several cases from
vaginal discharge, from the placenta, and from
fœtus.

The duration of the disease is very variable.
seldom lasts less than three weeks, more often
weeks or two months, and many cases are on re
which lasted one or two years. A lady, in w
case I have been interested and in which the diagn
is beyond doubt, has been familiar with her pre
symptoms since 1886! I cannot give you
average duration of the English cases, as some of t
are still ill, and of the termination of other cas
have not yet received information, but the ave
duration of the disease in Hardy's series of 95 recove
cases observed in the State of Iowa, U.S.A., was
weeks.

There is no doubt that the *average* severity of c
infected by the *Br. melitensis* is greater than
of abortus-infected cases, and the same differenc
usually reflected in the mortality-rates. Hug

gives the mortality of the Mediterranean cases as 2 per cent., whereas in Zeller's series of 626 German cases it only amounted to 0·6 per cent. On the other hand, Bierring reports a mortality of 2 per cent. among 150 cases in Iowa, but it must be remembered that in that State infection with the virulent porcine strains of abortus is common.

DIAGNOSIS.

Clinical.—I have already spoken of the clinical diagnosis when treating of the symptoms, so I will confine myself to reiterating the most helpful points, viz.: (1) The character of the temperature chart. (2) A symptom complex, including lassitude, headache, anorexia, and heavy sweats. (3) Prostration not nearly so severe as would be expected from the temperature.

Laboratory.—Positive agglutination to a titre of at least 1 : 100 is nearly always present, and tremendously high titres, which can be higher than in any other disease—e.g., 1 in 20,000—are often found. Blood culture is not always easy with organisms of the *abortus* variety, but it is always worth attempting, even when the pyrexia is moderate. A positive urine culture is less frequently obtained. A relative or even an absolute lymphocytosis is very common, and some degree of anæmia is usually present except in very mild cases.

The diseases for which undulant fever is most commonly mistaken in this country are influenza, enteric fever, and tuberculosis.

TREATMENT.

At present the principal treatment is symptomatic. Pyramidon in grs. 5 doses is useful for headache and for combating insomnia. Aspirin and the other antipyretics should be used with great caution. They have no permanent effect upon the fever—though the characteristic evening falls and the sweats are often wrongly attributed to their exhibition—and they tend to increase the depression which is often a marked feature of the later stages of the disease.

There is no specific treatment for the disease. The intravenous injection of mercurochrome, trypaflavine, Bayer 205, &c., have been tried with very little success, and are by no means free from danger. Killed vaccines of *Br. abortus* occasionally appear to help, but in my opinion they are best restricted to the later stages when the temperature is not rising above about 100° F., but refuses to remain at normal or below. Spicer's Edwenil has occasionally appeared to produce good results, but its action is uncertain, and I have lately heard of unpleasant symptoms produced by it.

Two points with regard to diet. First, the patient should not be kept on slops one moment longer than can be helped. Unless the symptoms and signs point to marked digestive derangement he will manage light, solid, or semi-solid food remarkably well, and it will help him to fight his feverish bouts and to make a more rapid recovery. Secondly, he should not be given raw milk, even certified milk, since it may very well contain the organism he is trying to fight. Efficiently pasteurised milk is quite safe.

ÆTIOLOGY.

The more I have reflected upon ætiology the more formidable has the problem appeared.

First, I may recall Kennedy's discovery of agglutinins for the *M. melitensis* in the milk and blood-serum of London cows. Commenting on his findings, Kennedy remarked: "I think the possibility of a melitensis infection of cows in this country should not be lightly thrust aside. I have heard of two cases of undulant fever in people who have never been out of England, and it is possible there are others undiagnosed." If Kennedy had known the close relationship between the *M. melitensis* and the *Br. abortus* he would no doubt have made inquiries about those cows and would have found that contagious abortion was present in the herds. This disease of cattle is widespread in every dairy-farming country, and is the cause of enormous loss every year to cattle owners. As it is not a notifiable disease in this country no reliable statistics are available, but there is no doubt that the infection is present in at least 80 per cent. of the dairy herds in this country, and some veterinarians and farmers of experience believe that 80–90 per cent. of our milch cows are affected. This does *not* mean that 80–90 per cent. of the cows are excreting the organisms in their milk at any one time, but a cow once infected seldom or never gets rid of the infection, and the organisms are at any time liable to appear in the milk.

We have little information with regard to the degree to which market milk in this country is infected, but Wilson and Nutt examined 488 samples of cows' milk in Manchester by guinea-pig inoculation (the most reliable method), and found that 5·7 per cent. of single milks and 8·8 per cent. of mixed milks contained the *Br. abortus*. I cannot here discuss the interesting problem presented by the curious discrepancy between this widespread infection of our milk-supply (pasteurisation, by the way, kills the organism, but in the provinces most milk is not pasteurised) and the small number of human cases reported. The same phenomenon has been observed in many other countries. In Denmark and other great dairying countries human infection by direct contact with infected cattle is very common, and it is difficult to believe that the same is not true to a certain extent in this country. What we do *not* know at present is whether sheep, goats, pigs, and horses in this country are infected. In France sheep and goats are the chief sources of human infection, and in some parts of the United States porcine infection is presenting a serious problem.

MEDICINE AND THE LAW.

Broken Hypodermic Needle.

ON March 31st an inquest was held on the body of a Bayswater postman who had suffered from acute attacks of bronchitis and asthma and who had been gassed three times during the war. His medical attendant gave evidence that, at the last of a series of hypodermic injections in the chest, the needle broke. He knew the needle had broken in the patient's chest and he explained the danger; but the patient, whose heart was in an extremely bad condition and who had had little food or sleep for a long time and was exhausted, refused to allow the broken piece to be removed either at the time or on the following morning. Post-mortem examination revealed a slight mark on the lung where apparently the needle had penetrated. The pathologist who gave evidence of the result of the examination was asked by the coroner (Mr. Ingleby Oddie) what was the duty of the doctor when a needle breaks. The witness replied that the broken needle should be removed at once; "they move so quickly that you don't know where they are"; he would not expect the needle to puncture the lung. The coroner, in returning a verdict of "Accidental Death," expressed his opinion that death was accelerated by the puncture of the lung. He added a rider that the needle should have been removed by the doctor who, he thought, had listened too much to the patient and not to his own sense of duty; "there are times when the patient's feelings should not dominate, and when it is the doctor's duty to insist." The medical practitioner whose conduct was thus reflected upon had already made it clear that he did insist and had fully appreciated the danger; but the patient had absolutely refused, saying that he wanted only to be let alone. Nobody suggested that the breaking of the needle was a negligent act; it was a mere accident, involving in itself no legal liability. While everyone will agree that a broken needle should be removed immediately, it is perhaps unnecessary to add that doctors have no power to compel a patient to undergo a surgical operation. A patient of mature age and of sound mind has the legal right to decide whether he will have a particular treatment or no treatment at all. No reflection whatever remains on the medical man.

Christian Science and Pulmonary Tuberculosis.

The patient's power to decide for or against medical treatment is illustrated afresh by a recent inquest at Battersea. A girl of 20, who had been for some months in a Christian Science nursing home at Harrow, had died of pulmonary tuberculosis. Giving evidence of the cause of death, Dr. Temple Gray said the girl had had the disease for about five years; had she had the usual hospital treatment early, there would have been the chance of a cure. Dr. Edwin Smith, the West London coroner, after opening the inquest on March 29th, adjourned it for a few days in order to obtain evidence of the treatment which the deceased had undergone. The superintendent of the Christian Science home at Harrow explained that the treatment consisted of prayer; the Christian Science visitor who had paid a daily visit to the deceased at the house in Putney where she died, gave the same explanation. A medical practitioner was called in about an hour before her death. The coroner asked whether this step was taken in order that a death certificate could be given. The suggestion was denied; the visitor gave the explanation that the other people in the house at Putney were not Christian Scientists and it therefore seemed fairer to them to call in a doctor. In answer to questions by the coroner, the Christian Science witness said that in cases of acute pain prayer could send away the pain and was in the witness's belief better for this purpose than morphia; in the case of bad teeth the patient would not be urged to see a dentist; a broken leg would have to be properly set by a surgeon, but scaldings or burnings would be left alone.

The jury found that death was due to general tuberculosis, accelerated by failure to obtain medical treatment. Their view, as elucidated by the coroner, was that somebody at some time should have intervened and insisted on proper medical treatment being given. Criminal neglect was not an element in the case, although, as the coroner pointed out, a finding of criminal neglect might have been justified if the girl had been a few years younger. She was, he said, little more than a child, and people should be careful not to impose their philosophies upon children. No doubt he had in mind Section 12 of the Children Act under which parents and persons in *loco parentis* are criminally liable for neglect if they wilfully neglect a child or young person by failing to provide medical aid. Apart from this provision of the Children Act, which applies only where the victim is under 16 years, there is a common-law liability on any grown-up person who, having undertaken the charge of a human creature helpless either from infancy, simplicity, lunacy, or other infirmity, allows that creature to die by wicked negligence. The deceased in the Battersea inquest case was 20 years of age and thus the Children Act was excluded; she also appears to have had strong views of her own and thus to have been far from helpless for the purpose of the common law. The coroner, however, was clearly obliged to make a full examination of the circumstances.

AUSTRALASIA.

(FROM OUR OWN CORRESPONDENT.)

PRESENTATION OF A MACE TO THE ROYAL AUSTRALASIAN COLLEGE OF SURGEONS.

AN event of unusual interest took place at the fifth annual meeting of the Royal Australasian College of Surgeons, when Mr. C. H. Fagge presented a mace—the gift of the Royal College of Surgeons of England—to the Australasian College. The ceremony took place in the Wilson Hall of the University of Melbourne in the presence of a large assembly. After the meeting had been opened by the Lieutenant-Governor of Victoria (Sir William Irvine) and Mr. Fagge had been introduced by the President of the College, he formally presented the mace. "In the name and by the authority of the Council of the Royal College of Surgeons of England," he said, "I ask you on behalf of the Fellows of the Royal Australasian College of Surgeons to accept this mace, which my colleagues hope may remain throughout the existence of the two Colleges an emblem of the brotherly affection which binds us together."

Describing the mace, Mr. Fagge said:

> "In designing the mace for the Royal Australasian College of Surgeons, Omar Ramsden has followed the general form and proportions of that of the Royal College of Surgeons of England, which was executed by His Majesty's goldsmiths. Of necessity the ornaments have been altered and appropriate emblems have been introduced.
>
> "By express permission of His Majesty King George V. the finial is formed by the Royal orb and cross; these emblems are supported by four arms or buttresses suggesting the form of a monarchial crown, and on them is woven a border of briar symbolising the thorny path which leads to greatness. The four panels around the head bear the arms of the Commonwealth of Australia and of the Dominion of New Zealand, of the Royal Australasian College of Surgeons, and of the Royal College of Surgeons of England, between which are oak decorations emblematical of the permanence of the institutions just mentioned. Beneath the head, which, as is fit, is supported by eight British lions, is a wavy strip to symbolise the separating seas. The universal decorations are the rose of England, the seven-pointed star and wattle of Australia, and the fern of New Zealand; and the staff bears the names of the donors—the 24 members of the Council of the Royal College of Surgeons of England in the year 1930-31. The cap bears *the Royal Arms, and round this is the legend that it is the* gift of our college to yours 'as brothers to brothers.'"

In accepting the mace, Sir Henry Newland said: "As President of the Royal Australasian College of Surgeons, I accept with pride and gratitude this most beautiful mace; the generous motives and fraternal sentiments which prompted the gift have touched our hearts. This young College, looking beyond the seas for inspiration, finds it in the ideals and example of the Royal College of Surgeons of England. This College is anxious, too, that the good repute of surgery shall be maintained, and that in the practice of its art the feet of its votaries may not stray from the ath of honour. May the beauty of this mace trengthen our purpose to adhere to all that it ymbolises."

Thirty-one new Fellows of the College were then resented to the President and formally admitted as ellows. Mr. George Robert Adlington Syme was hen presented to the President of the College and dmitted as a Fellow. It was explained that he would ot ordinarily have been admitted to the Fellowship ntil next year, but owing to the fact that this was the ccasion on which the first annual oration, in honour f his father, the first President of the College, was eing delivered, it was deemed fitting that he should be admitted then. Mr. Fagge then delivered the first George Adlington Syme oration, in which he reviewed the life and work of the late Sir George Syme and particularly the part he played in the formation of the Royal Australasian College of Surgeons. On the following day, the honorary degree of Doctor of Medicine was conferred on Mr. Fagge by the Senate of the University of Melbourne.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENT.)

CONTROL OF DRUGS IN INDIA.

THE report of the Drug Enquiry Committee has now been published, and its members, Colonel Chopra in particular, deserve congratulation on the promptitude with which they have produced an extremely comprehensive report; the interest in a subject is liable to die down if there is undue delay in publishing the findings. The report proper covers 170 pages, but its perusal is facilitated by a summary of the recommendations. The appendices, which cover another 250 closely printed pages, give the memoranda for which the Committee called and summaries of the evidence presented before them. The Committee recommend that control should be exercised over drugs, both those imported and those manufactured in India; that this control should be essentially a matter for the central government; that there should be a central laboratory in either Calcutta or Bombay, but in addition each province should have a laboratory in charge of a public analyst; that the provincial laboratories should test and report on drugs, other than biochemicals and organo-metallic compounds, submitted to them by the customs or other local authorities, or manufacturers; that the central laboratory should complement and supplement the work of the provincial laboratories, standardise methods of analysis for various climatic conditions and maintain stable standards, train analysts and carry out research work on indigenous drugs; that all manufacturers, importers, and traders in drugs should be registered; that government inspectors should be provided to collect samples for testing; and that legislation should be introduced regarding misbranding and adulteration of drugs. By way of financing these recommendations they suggested amongst other things *additional* import duties of 5 per cent. on all drugs, except crude chemicals, and of 20 per cent. on all patent medicines with undisclosed formulæ.

The Committee made a valiant effort to investigate the question of drugs used by the indigenous practitioners, the vaidyas and the hakims, but they found here such chaos existed that it was impossible to consider the inclusion of these drugs in any legislative measures to be recommended.

Their other proposals include some useful suggestion for the foundation of an organised and registered profession of pharmacy in India. At present there is little to prevent any totally untrained person dispensing and selling medicines or even taking up a post as dispenser in an institution. In most provinces there is no organised course of training for dispensers and in those in which this exists it is inadequate. They also urge the necessity for revising the present quinine policy and suggested that the possibility of producing a standardised cinchona-febrifuge which would be cheaper than quinine should be investigated.

TUBERCULOSIS.

Probably the most outstanding socio-medical problem of the day in India is pulmonary tuberculosis; furthermore it is one that is going to increase. History is, of course, repeating itself; while the more dramatic tropical diseases are being controlled by the efforts of the sanitarians and also by the increased urbanisation of the population, the latter is causing a serious rise in respiratory diseases, especially tuberculosis. The annual reports each year show more and more evidence of this. In Bombay, for example, the death-rate from tuberculosis is 1·1 out of a total death-rate of 21·2 per thousand. It is really more of a social than a medical problem and demands a revolution in the customs and habits of the whole population; especially those connected with purdah and housing.

RETRENCHMENT.

Medical research in India is coming into hard times. At the last annual research workers' conference the Director-General informed us that not only had the total research grant of 5 lakhs of rupees been cut, but in addition 1 lakh of the 2½ lakhs usually voted for the pay of permanent officers of the research department would have to be found out of capital this year. The research programme for 1932–33 had of necessity to be curtailed very considerably and a number of trained research workers dismissed. For a year or so, by drawing capital and exercising the strictest economy, the research fund will be able to carry on a modified programme, but unless the annual grant is soon restored all medical research work in India will cease.

The proposed Cholera Commission has been abandoned; this will be a disappointment to many people outside India who expect us to do something about the disease which, rightly or wrongly, they look upon as India's gift to mankind. Colonel F. P. Mackie, who was to have been in charge of this commission, has now retired, and we have thereby lost one of our ablest research workers. Colonel Mackie was one of the officers of the Indian Medical Service who joined Sir David Bruce's Sleeping Sickness Commission and during the last twenty years he has done valuable work in this capacity. His work in plague and sprue are well known. He was for many years Director of the Haffkine Institute in Bombay.

The All-India Institute of Hygiene was, as we foretold, not opened at the beginning of the year. The building was ready, but the Government, employing their usual dilatory methods, failed to sanction any expenditure so that no posts could be advertised. The Director-designate and his assistant are therefore in the position of administering one of the finest and best-equipped institutions in India, but one whose marble halls are entirely devoid of personnel. We now understand that financial sanction for opening four out of the promised six sections has been given, but that there are other difficulties, such as the selection committee for the staff, to be overcome. In these hard times there is probably sound reason to encourage these dilatory methods. We hope that the Rockefeller Foundation is satisfied that the Government of India are keeping their promise in spirit, if not in deed.

ATEBRIN IN MALARIA.

At the Calcutta School of Tropical Medicine atebrin, a new antimalarial preparation allied to plasmoquine, has been given a trial. In the first eleven hospital cases in which it was used there was almost immediate clinical improvement and rapid disappearance of the parasites from the peripheral blood. Like quinine it does not destroy gametocytes, but when it is given in conjunction with plasmoquine all forms of parasite disappear. In over fifty cases in which only a four-day course of atebrin was given under field conditions, the recurrence-rate was only 14 per cent.; some of these recurrences will have been reinfections as the patients were living continuously in a highly malarious place. The introduction of a real rival to quinine may have far-reaching effects.

(FROM AN OCCASIONAL CORRESPONDENT.)

SUPRARENAL EXTRACTS.

It is now 12 years since the "Muirhead régime" was inaugurated by Rowntree at the Mayo Clinic. Dr. A. L. Muirhead in spite of the treatment survived for less than a year, but the striking though temporary relief which he gained from the severe symptoms of Addison's disease encouraged further efforts. Rowntree continued the Muirhead régime (administration of adrenalin by hypodermic, rectum, and mouth to tolerance, and of whole gland or cortex by mouth) with temporary success in a little more than half the cases treated. *Frank A. Hartman, of Buffalo, N.Y.*, in 1927 precipitated from a watery extract of suprarenal cortex with sodium chloride a substance which he named cortin. The method of extraction was modified in June, 1930, by the use of alcohol and ether. The first human case was treated with this extract on July 8th, 1930, and since then six other cases have been treated in Buffalo by Hartman and his colleagues. The report of these cases [1] makes as dramatic reading as anything in the history of insulin. Their third case, for example, had a crisis during the course of treatment. The patient lost consciousness, his muscles went into spasm. Heart sounds were inaudible and respiration ceased "for a time." This man, not many days later, was able to walk more than a mile at a time without fatigue on a daily dose of the extract of 1200 g. of cortical tissue.

Rowntree and Green, of the Mayo Clinic, have treated 22 cases of Addison's disease with an extract prepared by the method of Swingle and Pfiffner (extraction with alcohol and benzene). The immediate results were excellent in 17 cases, but six patients have died (three while under treatment) and three failed to respond to treatment. The same extract, prepared at the University of Colorado Medical School, has been used by C. F. Kemper and P. A. Dickman.[2] In one case the results have been satisfactory. In another the use of the hormone apparently reactivated old tuberculosis so that the advantage gained was large neutralised.

The first attempt to produce the hormone on commercial scale has not been very successful, b efforts in this direction are being continued.

CHILD GUIDANCE.

Sad news is the announcement of the Commo wealth Fund that, owing to the necessity for retrenc ment, their support of the Child Guidance Institu of New York will be discontinued in 1933. In sense, however, the institute has served its purpos The value of child guidance work has been thoroughly recognised that there are now 232 clini in 34 States, most of them established during the la ten years. The high standards of the New Yo institute are reflected in these clinics all over t country. In addition to the 232 clinics abo mentioned, each with the full team of psychiatris psychologist, and psychiatric social worker, there a 442 "mental hygiene clinics" with at least o psychiatrist in regular attendance. The total 674 clinics served last year some 36,000 adults an more than 50,000 children. The National Committ for Mental Hygiene, which reports the above figure finds that "public and private organisations, paren and teachers, physicians, judges, clergymen, soci workers, all have recourse to the child guidanc clinic for help in the solution of juvenile problems.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

MENTAL TREATMENT BILL FOR NORTHERN IRELAN

THE lunacy law in Ireland has for all practic purposes remained unaltered since the passing the Act of 1875. The specialised treatment provid in public mental hospitals in Northern Ireland h been confined to persons definitely certified as unsound mind, and has thus been denied to tho who may be merely threatened with disease or w may be suffering from some temporary form of ment instability. The object of Part I. of a Bill, whi has just passed its second reading in the Parliame of Northern Ireland, is to enable cases of incipie mental disease to be treated in mental hospita without the necessity for certification and witho the intervention of anything in the nature of judic proceedings. Provision is made for voluntary trea ment and temporary treatment. Part IV. of t Bill enables public mental hospitals to provide clini at which extern patients may obtain advice and trea ment, and which will also enable discharged patien to receive the same advantages. It is proposed abolish certains terms which have hitherto be employed in mental illness and which have acquir a sinister and objectionable significance: "lunatic will be replaced by "person of unsound mind "lunatic asylums" by "mental hospitals," a "pauper" by "rate-aided person." With rega to admissions, it is proposed that persons of unsou mind may be received into a mental hospital on simple order of a magistrate supported by a medic certificate. In cases of urgency the patient may removed at once on the doctor's certification anticipation of the justice's order. In such case however, the authority to detain the patient limited to seven days, unless full procedure admission has meanwhile been completed. In t discussion on the Bill it was suggested that hom should be established where patients could be tak or treatment for a short period without having the eeling that they had been inmates of an asylum.

DUBLIN CORPORATION AND THE DUBLIN HOSPITALS.

In his financial proposals submitted to the Dublin Corporation the City Manager suggests the reduction by 50 per cent. of the amount of grants to such hospitals as are participating in the benefits of the Irish Hospitals Sweepstakes. He points out that the benefits received have been in fact far beyond all expectations. Last year the City Manager made a similar proposal to the Council, but the Council estored the full amount of the grants as in previous years. He asks the Council to consider the matter afresh this year.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

EDINBURGH BACTERIOLOGICAL SERVICES.

AT present the bacteriological work for the public health department of Edinburgh is done in four different institutions: the University, the Veterinary Department, the Royal Infirmary, and the City Hospital. Dr. Guy, the M.O.H., suggests that it would be best that so far as possible the University bacteriological department should undertake the service in future. This step has already been taken to some extent, for the town pays the University £550 a year for general bacteriological investigations. The Veterinary Department has two sections; it does microscopical work for detection of diseases and parasites in meat, &c., and biological work, involving the use of animals. These latter are used chiefly for the detection of tubercle bacilli in milk. It is now proposed that the biological work should be transferred to the University. The public health bacteriological work at the Royal Infirmary is entirely confined to venereal diseases. This task was undertaken by the Infirmary in 1922, being previously performed partly by the Infirmary and partly by the laboratory of the Royal College of Physicians. During the first year (1923) the number of specimens examined was 21,000, and at that time the Board of Health considered a sum of £2000 a reasonable amount to be paid by the town for the service. But the number of specimens last year was 54,000 and the sum paid remains about the same. Without dislocation the work could be undertaken by the University, and the whole question has been remitted to a small subcommittee, including the professor of bacteriology.

Many years ago, when the City Hospital was opened, Dr. Claude Ker stood out for a laboratory there. This was so obvious a necessity that a laboratory was established, and it is always in active use.

HOMICIDE BY A FEEBLE-MINDED BOY.

A thirteen-year-old boy lately appeared before Lord Anderson in the High Court of Justiciary at Edinburgh on a charge of having struck a small girl with a hammer and killed her. Dr. Dods Brown, physician-superintendent of the Aberdeen Royal Mental Hospital, Dr. J. S. Annandale, medical superintendent of the Aberdeen County Mental Hospital, Kingseat, and Dr. W. M. M'Alister, medical superintendent of Bangour Village, all certified that he was so feeble-minded as to be unfit to plead. Dr. M'Alister said that his intelligence was that of a child of about 8. The Solicitor-General announced he had been in consultation with the proper authorities about the boy's future, and Lord Anderson pronounced an order for detention during his Majesty's pleasure.

EDINBURGH HOSPITALS FOR WOMEN.

Bruntsfield Hospital has been recognised by the Medical Research Council as a centre for research in the radium treatment of diseases of women, and this has enabled the hospital to obtain radon from the Middlesex Hospital, and thus extend the scope of the work. The Council has also granted the Hospital a loan of 125 mg. of radium.

At the Elsie Inglis Maternity Hospital, investigation of maternal morbidity was continued during last year. A total of 1320 confinements were attended —965 in hospital and 355 on the district—an increase of 201 on the previous year. The out-patient department, a steel-house, of the Weir type, was taxed to its utmost, 15,719 attendances being registered there, an increase of nearly 2000. This was due to the growth of antenatal and postnatal clinics. The postnatal attendances were particularly gratifying, and the "follow-up" which was done there was of great value to both mothers and babies. In connexion with the 1320 confinements, there were only two maternal deaths, and the morbidity-rate was 3·8 per cent. This low rate is attributed to the special preventive technique which has resulted from the research carried on at the hospital during the last two years. In the extra nursery accommodation provided there is a Morgenthaler bed for premature or delicate infants, the only one of its kind in the country.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

A MEDICAL STRIKE.

SEVENTY assistant physicians, junior surgeons, and dressers, all employed by the dispensaries of the Jewish hospital, have refused to continue their hospital duties because the Board of the Jewish community, which maintains the hospital, refused to grant them even a modest salary. The Board argued that, in the present critical economic circumstances, when they have a tremendous deficit, it is impossible to encumber their budget with new expenses. Besides, doctors regard these posts as merely temporary, filling the gap between studenthood and private practice; apart from assistants employed in the hospitals, the rest are occupied in three out-patients' departments, working in various districts of Budapest. Furthermore, the Board established these posts directly for young Jewish physicians, to give them the chance of hospital experience, for until quite recently the municipal hospitals of the city, which are in a position to give work to hundreds of young doctors, did not employ Jews as assistants or junior dressers. The "strikers" put their case before the directors of the Hungarian Medical Association, which forbade its members to accept any unpaid appointment, and for the time being the directors regarded these posts as subjects of *cavete,* so that anyone who dared to take them would be unrecognised by the profession. At the same time they started negotiations with the Board of the Jewish community, but the latter, adhering to their resolutions, pointing to the miserable state of their community, more than 30 per cent. of its members being unable to pay their ecclesiastical taxes. The director of the hospital has appointed a small number of physicians-in-chief to attend the out-patient departments—all of which

CORRESPONDENCE

HÆMOLYTIC AND PERNICIOUS ANÆMIAS.

To the Editor of THE LANCET.

SIR,—In his final Goulstonian lecture (THE LANCET, March 26th) Dr. Witts discussed the hæmolytic anæmia of pregnancy. It is important to differentiate between this condition and pernicious anæmia associated with pregnancy owing to the difference in prognosis and treatment. The outstanding features in hæmolytic anæmia of pregnancy are the presence of free hydrochloric acid and enzymes in the gastric juice; a strong tendency to show rapid improvement after parturition to a normal blood picture, especially with suitable treatment; a maintenance of the complete remission even after discontinuance of treatment; and a disinclination to relapse in subsequent pregnancies. On the other hand, pernicious anæmia associated with pregnancy shows achylia gastrica, a grave tendency to fatal termination after parturition (if inadequately treated), and the necessity for continued treatment, the subsequent prognosis being as in ordinary cases of pernicious anæmia. I hope to show in a further paper that true pernicious anæmia occurs in association with and is not due to the gravid state per se. Cases of hæmolytic anæmia of pregnancy have been observed to respond to suitable treatment without further relapse even in subsequent pregnancies, despite discontinuance of treatment, whilst known cases of pernicious anæmia have been kept under observation throughout pregnancies and parturition on carefully adjusted therapy. I have found that in most cases satisfactory treatment consists of intravenous liver therapy, or oral administration of active[1] desiccated hog's stomach preparations. The former is eminently suitable where auto-hæmagglutination exists.[2] Cases of hæmolytic anæmia are able to discontinue all treatment after the blood picture has returned to normal, but in those of pernicious anæmia associated with pregnancy the treatment must be continued indefinitely, as in an ordinary case of pernicious anæmia.

I am, Sir, yours faithfully,

JOHN F. WILKINSON.

Royal Infirmary, Manchester, April 2nd, 1932.

PS.—May I be allowed, referring to another matter wholly, to comment on your annotation of April 2nd upon the paper by Dr. Klein and myself. It would appear as though we were stating that a hæmopoietic enzyme was present in gastric tissue based upon its thermolability above 45° C. We suggest that the substance is of an *enzyme-like* character and may possibly be an enzyme. Our evidence is based upon other observations, additional to the thermolability, such as behaviour in the presence of solutions of differing pH, necessity for a substrate, precipitation with alcohol, &c. We were particularly careful to augment the ordinary hospital diet in the special cases employed by the addition of protein in the form of meat given with the preparation under examination. The name "hæmopoietin" was chosen as not necessarily implying an enzyme character—the usual suffix *-ase* may be added if and when hæmopoietin is definitely proved to be an enzyme.

USE OF TUBERCULIN IN DIAGNOSIS.

To the Editor of THE LANCET.

SIR,—I have read with great interest Dr. D'Arcy Hart's report on the Value of Tuberculin Tests in Man.[1] His own investigations appear to be carried out with great care and accuracy, and his conclusions in general sound and logical. I was, however, a little surprised to find Pirquet's reaction described as practically useless, both in the preface (by the Medical Research Council) and by the author himself. Dr. Hart has not given Pirquet a chance. He has himsel performed no Pirquet tests at all, as far as I can see His condemnation is based partly upon the many bad results of former investigators using various "Pirquet tests," and partly on theoretical grounds.

As to the former investigators of the Pirquet test, many of them used tuberculin in various dilutions, the reactions were partly read after 24 hours, and their readings were not measured. When a man is found to be misusing a very simple test, it is not discreditable to the test, but to the man. On p. 13 of Dr. Hart's report we see that quite a number of scientists have had post-mortem controls of their Pirquet tests, which upon the whole confirmed the results of their tests Where are the human post-mortem controls of the Mantoux test? On p. 87 we see that Heimbeck's nurses became Pirquet-positive, "nearly all of them," within one or two years. Dr. Heimbeck has published Pirquet curves reaching 100 per cent. positive reactors among the adults in Oslo, not only among the working classes, but in the middle classes also.[2] The autho ought to be more careful before condemning a tes as "not delicate" enough, when it can give 100 pe cent. positive reactors in the apparently healthy population. Scheel and his school (especially Strom Ustvedt, Léikvam) have given the Pirquet test a more reliable basis than any other tuberculin test

To 10 c.cm. standardised tuberculin is added a drop o liquid carbolic acid. The tuberculin then will keep its fu power for months—at least in a cool, dark place. With glass rod implanted through the cork, one places a drop o the solution on the ether-cleansed skin of the arm. A quite superficial cut is made through the drop with lancet (5–10 mm. length; no bleeding). The arm is kep naked for 10 minutes, and the tuberculin is not washed o afterwards. After two or three days the reaction is read when it is doubtful or negative, the test is repeated at once (Two or three cuts are now to be preferred.) A reactio of at least 2 mm. erythema with palpable infiltration i positive. No control is necessary. Under ordinary circumstances further retesting has been of negligible value.

Our Pirquet test gives, without any repeating, a many positive reactions as 0·1 mg. Mantoux (1·0 mg.?) Nobody has clearly demonstrated as yet that the extr positives given by stronger Mantoux doses are rea reactions. Tuberculous persons have, as Dr. Har says, a marked tendency to non-specific intradermo reactions, partly of the delayed type. In order t master them he has used glycerinated broth controls But the control solution, which is not identical wit tuberculin minus the specific part of tuberculin, i not a control solution. His "extra-positives" ma be pseudopositives. He has chosen a reaction o 5 mm. as a borderline reaction. I cannot see tha this chosen borderline has any convincing scientifi basis.

The repeated Pirquet test is, in my opinion, th better test to-day. Its chief fault is its simplicity most people do not think they need to learn how to perform and read it. Very careful investigations are needed before the Mantoux test with strong concentrations is placed on a reliable basis.

PULMONARY TUBERCULOSIS IN CHILDHOOD.

To the Editor of THE LANCET.

SIR,—Dr. Bentley, in your issue of March 26th, states "that while the appearance of positive sputum disease in any child under 16 years of age is rare, the condition below the age of 10 is a medical curiosity." If he means by "positive sputum disease" a condition in which the child coughs out sputum containing tubercle bacilli his statement is no doubt correct, as children under 10 rarely do this; they swallow it. But if he means, as I believe he does, that tubercle bacilli are very rarely present in the sputum of young children I most definitely disagree with him. As has been said, children swallow their sputum, and consequently it can only be obtained by the stomach washout method described by Meunier and others. If this is done, however, a surprising number of positive cases will be found among young children and even infants. Recently, for instance, in five consecutive cases of the tuberculous type of erythema nodosum I found tubercle bacilli in three, aged 3, 5, and 7 years respectively, while Wallgren and many other continental writers have had the same experience with larger series of cases. Indeed this method is a great help in the diagnosis of tuberculosis in the child and should be used as a routine in all doubtful pulmonary conditions in childhood.

I am, Sir, yours faithfully,
W. ROBERT F. COLLIS.

The Hospital for Sick Children, Great Ormond-street, W.C., April 2nd, 1932.

TOXIC EFFECTS OF PHENOLPHTHALEIN.

To the Editor of THE LANCET.

SIR,—It may be of some interest to your readers to know that in certain cases phenolphthalein, which is now being widely used as an aperient, may give rise to a marked toxic reaction. In my own personal case a normal dose of it produces a violent urticarial eruption covering nearly the whole of the flexor aspects of the forearms, a collar-like circle round the neck, and in lesser degrees the calves and hands are affected. The reaction commences within half an hour of ingestion with intense tingling and itching, and the appearance of large circular areas of erythema which indurate into plaques and finally become blebs which exude serum, and the scars left are purple in colour.

There has lately been put on the market a pill, in which the name Aperione appears in the formula; this would appear to be responsible for the worst attack I have yet had. The manufacturers describe it as "non-toxic, somewhat similar to phenolphthalein." The Extra Pharmacopœia says: "Skin rashes reported in America from phenolphthalein" and "cases of toxic poisoning from submaximal doses," "such ill-effects have not been noted here." There appear to be at least seven names for the drug, the best known of these are Purgen and Laxoin. Aperione is yet another for what is apparently a very similar product.

My objects in writing are firstly that it seems to me that it should be possible for anyone to avoid a drug without having to consult a dictionary of trade names, if such a thing exists. Secondly, that it is possible that mine is not such a very rare case and that others may be wrongly attributed to food poisoning, as personally I had three attacks each due to a different preparation before being able to trace the cause. The same effect is produced in my case by Veramon but in a much milder degree, and I have known the latter to produce hæmoglobinuria in a patient who took a considerable quantity of it.

I am, Sir, yours faithfully,
F. A. PHILLIPPS.

Lower Sloane-street, S.W., March 27th, 1932.

THE PROBLEMS OF MARRIAGE.

To the Editor of THE LANCET.

SIR,—A recent letter in your columns, signed by the honorary medical secretaries of the British Social Hygiene Council, draws attention to the establishment of a Personal Problems Bureau, the consultant being Mrs. Neville Rolfe, the Secretary General of that Council.

In answer to a letter of inquiry from me as to whether the advice to be given "to those about to marry" would include at Mrs. Rolfe's discretion advice as to artificial measures of birth control, I am informed by Mrs. Rolfe that—

> "I am hoping to give assistance on the lines of the handbook on Preparation for Marriage to girls intending marriage. . . . . It does not appear to me that the question of birth control is likely to enter to any considerable extent. In the event of an individual requesting advice on methods they would be referred to the medical profession."

My desire in this letter is carefully to avoid the very disputable point as to whether such advice should ever be given "in preparation for marriage," and the still more debatable point as to whether that advice should be given under the arrangements now proposed.

But there arises for supporters of the British Social Hygiene Council a more general and extremely important problem. I was actively concerned in recommending that this Society (then called the National Council for Combating Venereal Diseases) should be formed as a semi-quasi-official body to undertake educational work conducing to the prevention of these diseases and the protection of the sanctity of family life, by the promotion of chastity and continence. This body has hitherto refrained from action which would imply approval of artificial birth control. The establishment, however, of a consultation centre at which advice in preparation for marriage may include advice on birth control—even if "not to any considerable extent"—we are told by the honorary medical secretaries has received "the full support and approval of the Social Hygiene Council." Furthermore, it is intended that part of the profits coming from these consultations shall be added to the funds of the British Social Hygiene Council.

This obviously is a new departure in policy of great significance, and cannot leave the position of the Council unchanged. Clearly it is now for every subscriber to its funds, including each contributing borough council and county council, to decide whether they are in sympathy with this departure of the

British Social Hygiene Council from the position of neutrality hitherto ostensibly maintained on this most controversial subject of birth control.

I am, Sir, yours faithfully,
ARTHUR NEWSHOLME.

The Athenæum, London, W., March 28th, 1932.

To the Editor of THE LANCET.

SIR,—In a letter appearing in the *Medical Officer* of April 2nd, Sir Arthur Newsholme comments adversely on "the establishment of a Personal Problems Bureau, the consultant being Mrs. Neville Rolfe, Secretary General of the British Social Hygiene Council." The decision of the Council authorising the establishment of the Bureau was taken after full and careful consideration and after consultation with representatives of the members of the British Medical Association. The plan for such a Bureau arose out of a series of lectures on Preparation for Marriage organised in coöperation with the Churches.

Sir Arthur Newsholme draws the conclusion that advice on artificial birth control is to be given by Mrs. Neville Rolfe. This is incorrect. In a letter addressed to him, from which he quotes, Mrs. Neville Rolfe expressly informed him that "in the event of an individual requesting advice on methods they would be referred to the medical profession."

The main objects of the Bureau are to assist parents wishing assistance in handling difficulties in sex training of children and to advise girls intending marriage.

Sir Arthur Newsholme further states that as the Bureau has been established with the sanction of the British Social Hygiene Council this indicates a change of policy on their part in regard to the subject of birth control. This again is incorrect. The policy of the Council has not been changed; advice on artificial birth control will not become part of its work in the future any more than it has been in the past, unless and until some future decision of the Council should reverse the present policy.

I regret that Sir Arthur in support of his personal views should have allowed himself to suggest that in these circumstances subscribers to the funds of the British Social Hygiene Council are called upon to reconsider their attitude to the Council.

I am, Sir, yours faithfully,
KENNETH M. WALKER,
Hon. Medical Secretary, British Social Hygiene Council.

April 5th, 1932.

*** The letter above from Sir Arthur Newsholme is identical with that published last week in the *Medical Officer*, to which Mr. Kenneth Walker refers.—ED. L.

THE DURATION OF THE RED LOCHIA.

To the Editor of THE LANCET.

SIR,—I have seen a considerable number of cases treated by Dr. Hobbs's glycerin irrigation with remarkable success. I think he is right in pointing out that there are degrees of sepsis and that it is not necessary to have a rise of temperature in all cases; and also that when red lochia persist after the seventh day following a confinement or miscarriage, this symptom should be looked upon with suspicion, and glycerin irrigation should be immediately carried out so that no septic focus is left in the uterus. There can be no doubt that these chronic discharges lead to a great deal of ill-health in women, and it is high time that the profession regarded these cases in a more serious light. It is chiefly as a preventive measure that I regard Dr. Hobbs's treatment as valuable. I agree with him that the long list gynæcological cases can be considerably reduced promoting free drainage from the uterus at the earli possible moment, instead of waiting for abnorm signs to make their appearance in the pelvis.

Again, we have all come across cases of fibrosi and arthritis dating from the last confinement miscarriage; and during the last few years in t vast majority of the cases I have seen there has be a history of a prolonged discharge which has remain untreated, and the symptoms of arthritis showed signs of diminishing until the discharge had be cured. The amount of illness amongst married wom under the National Insurance Act is causing gra concern to the friendly societies, and I believe a lar amount of this sickness could be prevented if Hobbs's treatment were more widely known; so th the practitioner who at present adopts the expecta attitude can be provided with a simple a *satisfactory method of treatment in these cases.*

I am, Sir, yours faithfully,
Kensington, April 5th, 1932. RONALD CARTER.

CALCIUM CONTENT OF THE LIVER.

To the Editor of THE LANCET.

SIR,—Miss Wright and I are interested in t *calcium content of the liver.* Might I be allowed request any of your readers, who may be in t position to do so, to send us portions of liver fro women dying from eclampsia or hyperemes gravidarum? We should like roughly ½ lb. of live from each lobe if possible, and the material witho any preparation may be wrapped in waterpro material and posted to either of us at the Pharm cology Department, University College, Gower-stree W.C.1. It is because the method is prolonge the apparatus specially made, and eclamptic live are difficult to obtain, that I have ventured to ma this request.—I am, Sir, yours faithfully,

April 5th, 1932. G. W. THEOBALD.

ANCOATS HOSPITAL, MANCHESTER.—At the annu meeting of this hospital on April 1st, it was stat that the year's working showed a deficit of £13 which, however, was largely covered by legacies. T medical board's report stated that the staff believed th waste of time in the out-patient department could only avoided by rigidly regarding this department as a pure consultative centre.

ROYAL VICTORIA HOSPITAL, BELFAST.—The annu meeting of this hospital was held on March 23rd wi Lady Pirrie in the chair. During the year 1931, 66 cases were treated in the wards, and this was t highest number yet recorded. At the extern departme 47,603 new cases were examined. The total cost of mai tenance and administration was £57,347, and the tot receipts were £56,571. The daily average number of be occupied was 410. During the year 168 road traffic a motor accident cases were admitted; their total cost maintenance was £2175, and of this amount the hospit was paid only £658. A piece of ground has been rente to the Queen's University for the purpose of erecting pathological institute which will eventually be connect with the hospital by a covered way, and under arrangeme with the Queen's University the bacteriological and bi chemical departments of the hospital will be transferr there. Great progress has been made in the erection the new maternity hospital; but £50,000 is still requir to complete the building and to purchase equipmen The board of management and medical staff are anxio to provide accommodation for patients of moderate mea by the erection of a paying patients' block. The Children Hospital, situated in the same area, is almost finished. grouping and equipment this colony of allied institutio will, it is hoped, be almost unrivalled in the British Isles.

OBITUARY

GEORGE MATTHEW ROBERTSON, M.D., C.M. Edin., F.R.C.P. Edin.

WE announced the death last week of Prof. G. M. obertson, which occurred on March 26th at his esidence. Tipperlinn House, Morningside. He had een in failing health for some time and had intimated is intention of retiring from his appointments in the ourse of this year.

George Matthew Robertson was born in 1864. the on of Col. Robertson of Liddington Hall. Guildford. Ie received his preliminary education at Madras ollege, St. Andrew's. and completed his medical raining at the University of Edinburgh, where he raduated M.B., C.M. in 1885. He served for a period as resident physician at the Royal Infirmary, Edinburgh. and having by that time decided to practise as an alienist took a post under Sir Thomas Clouston, then superintendent of Morningside, where he became senior resident assistant. He obtained the diploma of M.R.C.P. Edin. in 1891, and in 1892, being then the senior resident at Morningside. he was appointed physician-superintendent of Murthly Asylum. Here he introduced a villa system of housing the mentally afflicted, and made a considerable name for himself both on the scientific and administrative side of his specialty.

PROF. ROBERTSON.

[*Photograph by Yerbury & Son.*

In 1893 he was elected to the fellowship of his College and in 1899 he was appointed physician to the Larbert Asylum, but shortly afterwards he succeeded his former chief, Clouston, as physician-superintendent of the Royal Edinburgh Hospital for Mental and Nervous Disorders, as Morningside is now termed. This was in 1903, so that for practically 30 years Prof. Robertson was in charge of the institution whose development owes so much to his energies. At the date of his appointment Morningside consisted of the two institutions West House and Craig House, and its reputation under Clouston was a very high one; but the scope of its activities was insufficient to meet the ideals of Robertson, who was a pioneer in the advocacy of the treatment of the insane as sick people—victims of disease in the same way as they might have been the victims of any other disease, and requiring in the same way treatment directed to alleviation and cure. To treat the mentally afflicted as sick people was his unswerving intention, and he was fortunate in finding in the Managers of the Royal Mental Hospital men who supported him in his views, and indeed suggested certain of the channels through which they might be carried out. For some time he had under consideration a scheme, with which his name is always associated. for the opening of nursing homes where patients suffering from incipient mental disorders could be watched, and preventive measures be employed when they still were likely to be efficient. In 1917 the Managers, accordingly, in support of Robertson's scheme, purchased houses in Edinburgh and opened them as private nursing homes, staffed with matrons and hospital trained nurses, to which the mentally sick were admitted on a system similar to that employed in dealing with patients suffering from other illnesses. The success of the institutions, whose inmates were mainly drawn from the upper classes, was such that ten years later the Managers of the Royal Mental Hospital built and opened the Jordanburn Nerve Hospital, where patients of all social grades could be received for examination and could remain for treatment, at nominal rates, on the recommendation of the examining physicians. A lecture theatre for students was attached to this hospital which became the centre for instruction in psychiatry at the University of Edinburgh, and Robertson was appointed lecturer in mental disease to the University. In 1920 the University raised the lectureship to the status of a professorial chair, when Robertson was immediately appointed to the post.

Probably none of his activities gave him greater pleasure than the teaching of students, and by the advances he made in psychiatric education at Edinburgh University he has erected to himself an enduring monument. He prepared his lectures with care, and he took great pains to make his subject interesting and palatable. As a lecturer he was able, with no loss of dignity, to adopt an easy and intimate manner with his class. The quality of his mind made abstract thought difficult for him. and in his lectures he did not indulge in abstruse theorising, which he believed only served to confuse his listeners. His teaching was thoroughly practical, and his aim was to equip the students with the knowledge which would enable them to deal in an enlightened manner with the cases of mental illness they would afterwards meet in practice. In his teaching he made full use of his wide clinical experience, and his phenomenal memory enabled him to enliven his lectures with graphic clinical pictures of cases which had passed through his hands. He recognised that the only way to teach psychiatry was to bring the student into intimate contact with actual cases of mental illness, and so he not only gave excellent clinical demonstrations, but he made his students attend in the wards of the Royal Edinburgh Hospital, and at the Psychiatry Out-patient Clinic of the Royal Infirmary. and take an active share in the treatments.

A special feature in Robertson's far-ranging services to psychiatry was his deep interest in the psychology of childhood, and at his instance a house was furnished in Morningside Park for the reception and study of these little patients under the supervision of Prof. James Drever, reader in psychology in the University of Edinburgh, and a recognised authority on the psychology of childhood.

Robertson's position was acknowledged by the prominent place that he occupied in the official medical world. At the Royal College of Physicians of Edinburgh he was at different times Cullen Prizeman and Morison lecturer and in 1926–27 President. At the Royal Medico-Psychological Association, where he was a medallist and twice prizeman, he was Maudsley lecturer, and in 1922 he occupied the president's chair. He was a corresponding member of several continental societies and the University of St. Andrews conferred the degree of LL.D. upon him. He was an infrequent writer, but an untiring exponent of his science at social and scientific gatherings, where he enjoyed the greatest popularity due to his personality.

Dr. Bedford Pierce writes: "In paying a tribute to the value of Prof. Robertson's services to psychological medicine, I would specially refer to his work in connexion with the Royal Medico-Psychological Association. He was an active member supporting all efforts to improve conditions of treatment, the better training of medical students and of nurses. Those who attended the annual meeting of the Association when he was president will not readily forget the excellent arrangements, the high standard of the discussions, and the president's hospitality. He had the good fortune to possess a genial disposition and he was a delightful host. He was an excellent and fluent speaker, and was a far-seeing man and in matters of policy his judgment was of marked value. In controversy he was always courteous, and took pains to induce others to accept his opinions. He seemed rarely to forget he was a Scotsman, and delighted in his speeches at the Association meeting to explain how Scotland was far in advance of England in the management of mental hospitals and indeed in any direction that might be under consideration. But local patriotism did not exclude wider interests. He edited Dr. Barclay's translation of Kraepelin's monumental work, and recognised Bayle as the discoverer of general paralysis of the insane. Robertson filled with marked ability his important positions. Many have marvelled how it was possible for one man to direct successfully the medical administration of practically three mental hospitals—Craig House, West House, and later Jordanburn—whilst holding the chair of psychiatry and at the same time responding to the demands of a considerable private practice. It is to be feared that at last this was too great a task for even his exceptional powers and so we mourn his loss."

The following appreciation of Prof. Robertson reaches us from a colleague and friend: "Prof. G. M. Robertson's death will cause widespread sorrow to his many friends in this country and abroad, but none will lament his death so much as those who have had the privilege of working with him or serving under him. In many ways he was an exacting chief. He expected a great deal from his assistants, and while he resented inefficiency, no one was readier than he was to appreciate and reward merit and industry. He treated his assistants as colleagues rather than subordinates. He did not demand a slavish obedience from them; he rather encouraged initiative and self-reliance, even from his junior assistants. Like most men of really wide knowledge and experience, he was tolerant of the views and opinions of those less experienced than himself. Nothing gave him greater pleasure than to discuss a problem with his staff, and he was receptive of suggestions no matter from what source they came. He took a deep personal interest in every member of his staff, and he inspired in them loyalty and affection. He rarely failed to animate those around him with his own enthusiasm. His interest did not cease when they were no longer serving under him, for he followed their careers with keen interest, and kept in close touch with them. His qualities would have distinguished him in any walk of life. He was a man of action; with a fearless and buoyant mind. He was imbued with the true spirit of adventure. For him the successful completion of an undertaking was but a prelude to another venture. His life was a crusade against reactionary tendencies and archaic methods of treating mental disease, and the value of the reforms he effected is now universally acknowledged. His life was devoted to the improvement of the methods for treating the mentally afflicted. He had great social gifts. He was a delightful host, and a vivacious conversationalist. His cheerfulness and good humour never deserted him, and he inspired confidence and affection in all who came in contact with him. It is difficult to realise that he is gone, and it is certain that his vital personality will continue to exert an enduring influence on all who were intimately associated with him.

> "And now that thou art lying, my dear old Carian guest,
> A handful of grey ashes, long, long ago at rest,
> Still are thy pleasant voices, thy nightingales, awake,
> For Death, he taketh all away, but them he cannot take."

Prof. Robertson married Lilias, daughter of the late Daniel Ritchie, who died in 1914, and is survived by one son.

RUSHTON PARKER, M.B., B.S.Lond., F.R.C.S. Eng.,

PROFESSOR OF SURGERY IN THE UNIVERSITY OF LIVERPOOL.

THE death of Mr. Rushton Parker, the veteran professor of medicine in the University of Liverpool, was announced last week in the 86th year of his age. He had held the chair of surgery since the development of University College, Liverpool, into the University of Liverpool.

Rushton Parker was born in Liverpool in 1847 the eldest son of a medical practitioner in the city, and there received his preliminary education, proceeding to University College, London, to complete his medical studies. He was a distinguished student and the recipient of scholarships and medals, was house surgeon to University College Hospital in 1869, and demonstrator of anatomy in the medical school during the two following years. He then returned to Liverpool on receiving the appointment of surgeon to the Stanley Hospital, an institution which he served for six years, until in 1878 he was appointed assistant surgeon to the Royal Infirmary. Here he was already well known, for he had been a demonstrator in the medical school attached to the infirmary during the period that he was on the staff of the Stanley Hospital. At the school he now became lecturer on surgery and teacher of practical and operative surgery, and in 1882, while still assistant surgeon at the infirmary, he became professor of surgery at University College, Liverpool. This college, founded in 1881 and

PROF. RUSHTON PARKER.

[*Photograph by J. Bacon & Sons*

incorporated into Victoria University in 1884, became by Royal Charter the University of Liverpool in 1903, since which date Rushton Parker held the chair of surgery.

Throughout his long career Rushton Parker was especially interested in mechanical surgery, while more than 50 years ago he did pioneer work in the surgery of tuberculosis and in the perfecting of the radical treatment of hernia. He published throughout a long range of time, notes on work which had come under his own hands, notably a paper on the extirpation of enlarged lymph glands which appeared in the *British Medical Journal* and another which was contributed to the proceedings of the Royal Medical and Chirurgical Society on ununited fractures healed by bone particles. In "Heath's Dictionary of Surgery" he wrote the articles on Peritonitis and on Diseases of the Nose, and in the *Clinical Journal* he published a practical paper on simple and compound fracture of the nose. He was also the author of a communication to the International Medical Congress of 1881 on the use of Thomas's splints.

To many generations of Liverpool students and doctors Rushton Parker has been a familiar figure, and those who never knew him in his active professional days will long recall his flowing Inverness cloak and sturdy short-stepped gait. "Now that he is no more among us," writes a member of the present University staff, "we hear stories of a kindly nature quite unsuspected by those who were brought into contact with him only as casual acquaintances. It was a kindliness extended not only to his friends, but to any who crossed his path who in the way of duty or by stress of fortune found themselves in difficulty, loneliness, or trouble." In his early days Rushton Parker was marked by openness of mind and a readiness to see and admit the value in what was new. Lister's principles were recognised at once by him as right, and were introduced into the practice at the Infirmary immediately. He was one of the first to recognise the genius of Hugh Owen Thomas and William McEwen, and that at a time when the former was not a persona grata with the profession at large. It was owing to his interest and encouragement that Thomas was persuaded to publish an account of his splints, and when the time came for the professor to accept his portrait from his admirers there was found faintly outlined, at his own request, upon the portrait a Thomas's splint.

Apart from his professional attainments he was a man of wide culture. He loved good books and good music and he was also a linguist of considerable parts. He was a member of the Geological Association and the Liverpool Geological Society.

Rushton Parker married in 1884 Catherine Elizabeth, the daughter of the late Mr. Thomas Bickerton, who predeceased him in 1924.

DR. MARY CONSTANCE TUGMAN, who with her mother was knocked down and killed by a motor lorry in Newbury, Berks, on March 6th, was 33 years of age. Five years ago, having qualified from the London School of Medicine and St. Mary's Hospital, she decided on hearing from her uncle, the Archdeacon of Johannesburg, of the terrible need of the native mothers on the Rand, among whom the infant mortality-rate is 750 per 1000, to go out as a medical missionary. Her mother, who had done rescue work in England and South Africa, and had trained as a midwife, went with her, and together they opened a clinic in a back room of a native priest's house in Sophiatown, where they weighed babies, instructed native mothers in the care of their children, and treated the sick. Dr. Tugman also visited patients in their primitive homes, travelling about, often alone, in a motor-car with her equipment. In this way she treated 6000 cases in one year. Two other women doctors joined her later, and together they opened and took charge of ten clinics. Work on a nursing home was begun in 1930, but Dr. Tugman did not see this completed.

DR. ALEXANDER DOUGALL BLACKADER, whose recent death is announced, was a graduate of McGill University, Montreal, and won a distinguished position in the University and the city. He was professor of therapeutics and pædiatrics, and as a specialist in children's diseases had a wide reputation. He became editor of the *Canadian Medical Association Journal* after the war, when Sir Andrew Macphail retired from this post, and held the editorship until recently with marked success. On his resignation last year, the Association established a Blackader lectureship in Pædiatrics in the University.

In his 59th year Dr. CHARLES HERBERT MOORHOUSE has died at Leeds where for many years he had been prominent both as practitioner and citizen. He received his medical education in the town, and on graduating as M.B. Vict. in 1897 took up resident appointments at the General Infirmary before entering on practice. His direct association with public affairs began in 1910 when he unsuccessfully sought election to the City Council. Not long afterwards he succeeded, and in the years that followed he twice became an alderman. For nearly 11 years he acted as chairman of the health committee, and he was made a justice of the peace in 1924. He leaves a widow and one daughter.

DR. FRANCIS HENRY BODMAN, who has died at Bristol at the age of 87, was senior member of a large medical family. A graduate of Aberdeen, where he took the degrees of M.B. in 1870 and M.D. in 1872, he also studied at St. Bartholomew's Hospital. Entering practice in Devizes he became physician to the North Wilts Dispensary, but in the 'eighties moved to Clifton, where he became connected with the Bristol Homœopathic Dispensary and later the Homœopathic Hospital. Here he was a member of the staff for many years, as are two of his sons, Dr. J. H. Bodman and Mr. C. O. Bodman, at the present time. A third son, Dr. Alan Bodman, lives in Lisbon, while two grandsons are carrying on the medical tradition of the family in Bristol.

DOUBLE INFECTION.—In his annual report Dr. C. Barclay Reekie, medical superintendent of the West Fife infectious diseases joint hospital, states that there was only one death in the scarlet fever wards, and that there have been only two out of the 1885 cases admitted during the last four years. There had, however, been an increase in the mortality-rate from diphtheria, mainly as the result of the lack of early treatment. The medical staff are anxiously awaiting the completion of the observation block with 24 cubicles and accommodation for 48 patients. The eight existing observation wards have only attacked the fringe of the difficult problem of double infection. The hospital was designed for the preferential treatment of scarlet fever, diphtheria, and enteric fever, but the remarkable change in the incidence and rate of mortality of infectious diseases and the extension of the list of notifiable diseases have made the provision of cubicle accommodation necessary.

MEDICAL NEWS

University of Aberdeen.

On March 30th the following degrees and diploma were conferred:—

LL.D. (Hon.).—Sir Buckston Browne, F.R.C.S.

D.Sc.—R. A. Cleghorn, M.D.

M.D.—Robert Dawson and H. C. R. Gunter.

M.B., Ch.B.—Sheila Thomson (with second-class honours), Alexander Anderson, D. G. Anderson, J. L. Carle, J. J. Elphinstone, Agnes K. Forbes, Andrew A. Forbes, George Geddes, William Goldie, A. A. Harper, J. W. A. McIver, J. R. M. Mackie, H. W. T. Martin, David Middleton, W. N. Murray, J. C. Niven, J. W. Pickles, W. S. Pollock, E. D. Robb, John Warrack, and D. B. Watson.

D.P.H.—M. W. Keith.

University of Edinburgh.

At a graduation ceremonial on June 30th it is proposed to confer the honorary degree of LL.D. on Mr. D. M. Greig, conservator of the museum of the Royal College of Surgeons of Edinburgh, and on Emeritus Professor Arthur Robinson, who has lately retired from the chair of anatomy in the University.

University of Glasgow.

Among recipients of the honorary degree of LL.D. on June 15th will be Dr. Alessandri Roberto, professor of surgery in the University of Rome, Dr. A. Brown Kelly, consultant for diseases of nose, throat, and ear at the Glasgow Royal Asylum, and Sir James Alfred Ewing, late principal of the University of Edinburgh.

University of Birmingham.

Five Withering lectures on Some Aspects of Human Biology will be given by Mr. C. J. Bond, F.R.C.S., in the Medical Faculty Buildings at 4 P.M. on Wednesdays, April 20th and 27th, and May 4th, 11th, and 25th.

Post-graduate Course in Cardiology.

At the Liverpool and District Hospital for Diseases of the Heart a fortnight's course in cardiology will be held from April 27th to May 10th. The sessions will be from 3.30 to 5.30 P.M. Early application should be made to Miss Lewis, the secretary, at the hospital.

British Institute of Philosophy.

A course of six weekly lectures on the Foundations of Moral Values will be given by Prof. J. H. Muirhead on Wednesdays at 5.45 P.M., beginning April 27th, at University Hall, 14, Gordon-square, London, W.C.1. A syllabus can be obtained on application to the director of studies at University Hall.

International Congress of Psychology.

The tenth International Congress of Psychology will be held at Copenhagen from August 22nd to 27th. We are informed that after the congress there will be opportunities of visiting certain German and Austrian institutes of psychology. Elaborate programmes are being arranged for periods up to Sept. 14th, and particulars may be had from Prof. Dr. D. Katz, Moltkestrasse 13, Rostock (Meckl.), Germany.

National Institute of Industrial Psychology.

Dr. C. S. Myers, F.R.S., principal of the Institute, will give three lectures on Psychological and Social Factors in Business Rationalisation at 5.30 P.M. on Wednesdays, May 4th, 11th, and 18th, at the London School of Economics and Political Science.

National Institute of Child Psychology.

This institute (formerly the Children's Clinic) has been obliged to cut down some of its activities owing to shortage of funds. It is, however, carrying on at 20, Warwick-crescent, London, W., with a smaller staff and a reduced number of cases, selected for their special clinical interest.

Auxiliary R.A.M.C. Funds.

The annual meeting of the members of the Auxiliary R.A.M.C. Funds will be held at 5 P.M. on Friday, April 22nd, at 11, Chandos-street, Cavendish-square, W.1, when the officers and committee for the current year will be elected.

Central Association for Mental Welfare.

A course for those engaged in the training of mental defectives will be held in London from July 2nd to 23rd, under the auspices of this association (24, Buckingham Palace-road, S.W.1). It will consist of three weeks' training in methods of teaching defectives in occupation centres and institutions, including special methods for low-grade types. Students are recommended to supplement the course, if possible, by spending a week in a certified institution for defectives; the association will make arrangements for this additional week if desired.

London Hospital Medical College.

The Liddle triennial prize, of the value of £120, is offered for an essay on the Causes and Differentiation of Anæmias. Particulars will be found in our advertisement columns.

King's College Department of Anatomy.

The Hambleden Department of Anatomy will be opened at King's College at 3.30 P.M. on Wednesday, April 27th, by the Earl of Athlone, Chancellor of the University of London.

Royal Sanitary Institute.

A meeting will be held at this institute, 90, Buckingham Palace-road, London, S.W., at 6 P.M. on Tuesday, April 12th, when a discussion on the Bacteriology of Milk and Methods of Sampling will be opened by Dr. T. S. Keith and Mr. H. W. Walters.

National Safety Congress.

This congress, arranged by the National "Safety First" Association (119, Victoria-street, S.W.), will be held in London from May 4th to 7th. There will be a session on Safety in the Home at 10 A.M. on Thursday, the 5th, in the Caxton Hall, Westminster.

Leeds Maternity Hospital.

Last year there were 1715 births in the Leeds Maternity Hospital and 631 in the branches, an increase of 116. Of the total births in Leeds 32 per cent. took place in the Maternity Hospital.

Anaphylaxis from Bee-stings.

In connexion with the correspondence on this subject in our issues of March 12th and 19th, we are informed *that at the annual meeting of the Apis Club (the* English branch of the International Organisation for the Study of Bee-keeping) Dr. Keith Thompson will give an address on Bee Venom. The meeting will be held at St. Bride's Institute, Fleet-street, London, W.C., at 3 P.M. on Wednesday April 20th, and members of the medical profession are invited to attend.

The Portrait of Dr. Alfred Cox.

Sir Arthur Cope's portrait of Dr. Alfred Cox has been transferred to Burlington House, and we are asked to advise those of our readers who see the picture at the exhibition and who desire copies, to communicate with Mr. Bishop Harman at the B.M.A. House, Tavistock-square. The charges for these copies, carriage paid, are: engraved *artist's proof (signed), £4 4s.; a print, £2 2s.*; photogravure (17 in. by 14 in.), 14s.; oil facsimile (12 in. by 9½ in.), 6s.

"Journées Médicales," Evian.

The Medical Society of Evian-les-Bains announces the holding, for the second time, of "Journées Médicales" in the spa during the month of September, 1933. Prof. Lemierre will preside over the sessions, which will be *devoted to the study* of Renal Insufficiency. In *this* connexion the Société Anonyme des Eaux Minérales d'Evian-les-Bains offers a prize of 10,000 francs for the best original work on the Semeiological Value of Tests of Provoked Diuresis. The prize is named the Prix Chiais, in memory of the well-known hydrologist. The competing manuscripts must be anonymous, and reach the head office of the Société des Eaux Minérales d'Evian, 21, Rue de Londres, Paris (9e) not later than May 15th, 1933. They must be written in French. All information concerning the competition may be obtained from the Society at the above address.

St. Mary's Hospital Institute of Pathology.

A course of lectures on Pathological Research in its relation to Medicine will be given at the Institute of Pathology and Research, St. Mary's Hospital, London, W., at 5 P.M., on Tuesdays from April 26th to June 14th. Sir Almroth Wright, F.R.S., principal of the Institute, in opening the series, will speak on a New Body of Immunological Doctrine. The subsequent speakers will be Dr. Hugh Cabot, of the Mayo Clinic, on the Present Position of Transurethral Prostatectomy; Major Meurice Sinclair on Fractures of the Lower Extremity; Prof. E. D. Adrian, F.R.S., on the Nervous *Mechanism of Respiration*; Prof. Martin Hahn, of Berlin, on the Lübeck Trial and the Scientific Principles involved in Calmette's Inoculations; Dr. Donald Hunter, on the Clinical Significance of Studies in Calcium Metabolism; Sir Henry Dale, Sec. R.S., on Recent Work on Hormones of the Circulation; and Prof. R. T. Leiper, F.R.S., on Helminth Migrations. The lectures are open to members of the medical profession and students without fee.

NOTES, COMMENTS, AND ABSTRACTS

EPIGASTRIC PAIN.*

By T. C. Hunt, M.D., M.R.C.P.,

PHYSICIAN IN CHARGE OF OUT-PATIENTS, ST. MARY'S HOSPITAL.

Epigastric discomfort or pain, with or without a relationship to food, is commonly attributed to a primary gastric cause, but many other conditions may produce gastric disorder or gastric symptoms.

The diagnosis must therefore be made in the first place between three great groups of causes; (1) general diseases; (2) local diseases elsewhere in the abdomen; (3) primary gastric diseases. Full examination of the patient as a whole will generally exclude the first group; mild or severe heart failure, general arterio-sclerosis, renal disease, pulmonary tuberculosis, and tabes dorsalis, for example, can be excluded by a full clinical examination of every system in the body. The commonest non-gastric abdominal lesions to cause epigastric pain and discomfort are cholecystitis, appendicitis, and colitis. The symptoms alone may not always be sufficient to differentiate these, but careful inquiry into actual colic, jaundice, right iliac or hypochondriac pain, pyrexia, or relation of the pain to defæcation or passage of flatus may help.

If, however, the condition appears to be gastric without features suggesting disease elsewhere in the abdomen, there are four main possibilities: (1) carcinoma; (2) ulceration of the stomach or duodenum; (3) gastritis; (4) primary nervous or functional disorder of the stomach with or without secondary gastritis. I propose to consider a few points only in the diagnosis of these four conditions.

Carcinoma.

The typical picture of carcinoma ventriculi is so well known that I shall only refer to one or two special symptoms. Carcinoma must, of course, be suggested at once by any freshly commencing indigestion in a patient over 40. It is not, however, very uncommon for growth to appear after a long history of dyspepsia due to gastritis, so that the length of history is not in itself any proof that the condition is non-malignant. Secondly, pain—at least at first—is far less common than mere discomfort, which is apt to be marked soon after meals, but may persist even when food is withheld. The anorexia found with it is too well known to require any comment. Severe pain, nausea, and vomiting are generally late symptoms.

A palpable tumour in carcinoma of the stomach is a late sign. It is often possible, however, to feel a small pyloric growth when the patient is standing, even if it is impalpable lying down; examination in the erect position is a useful aid in diagnosis. The radiologist, when screening a patient standing, not infrequently feels a lump which has not been felt by the physician examining his patient on the couch. On the other hand, in general, the larger the primary stomach growth the fewer the metastases, and vice versa, so that a large growth *does not necessarily* mean an inoperable one. Even when seen at operation, tumours are apt to be deceptive, as in a case I saw recently.

A tumour of the pylorus was found to be inoperable as long ago as 1896 by one of the surgeons in this hospital, and the patient brought to me in 1931 an excellent account of his case, shown in 1897 at a medical meeting in London, emphasising the remarkable benefit to be gained by gastro-enterostomy with a Murphy's button in restoring nutrition in hopeless cases of malignant pyloric obstruction! It was, of course, a cicatricial pyloric ulcer, and the patient is quite well to-day, having had no further gastric symptoms.

There are three less widely recognised symptoms that may occur early and are worthy of comment: bleeding and anæmia, fever, and thrombosis.

(1) *Bleeding* is very frequent in the shape of slight continuous loss without any gross hæmatemesis or melæna. It can often only be detected by the chemical tests for occult blood, the stools appearing normal to the naked eye. Unsuspected bleeding may lead to anæmia, which is not uncommonly the predominating symptom. *Any unexplained anæmia, with or without abdominal symptoms or wasting in a man over 40, should at once raise a suspicion of gastric carcinoma.* The appearance of the patient often resembles pernicious anæmia. There may be nothing abnormal to feel in the abdomen, as in the following case.

Male, aged 58. Weakness and dyspnœa for five months. No indigestion except for one day seven months previously. No pain or vomiting. Appetite good. Very pale. Blood count, 3,600,000 red cells; hæmoglobin, 40 per cent. Achylia gastrica. No abdominal tumour felt. Occult blood present. Post mortem small pyloric carcinoma with secondary deposits in lungs.

On the other hand, there may be a large tumour which may be mistaken for a spleen, as in the following case.

Male, aged 58. Phlebitis both legs, and œdema ten months. No anorexia; no epigastric discomfort or pain. No vomiting. Weakness and pallor six months. Blood count 4,400,000 red cells: hæmoglobin, 50 per cent. Large tumour in left hypochondrium at first thought to be splenic. X ray: extensive carcinoma of body of stomach. Occult blood present.

(2) Some *fever* is quite common—generally of a low intermittent type, so that occasionally the case resembles that interesting disease, "P.U.O." Any serious degree of fever is highly suggestive of metastases in the liver, of which it is a very frequent (some say a constant) feature.

(3) *Peripheral venous thrombosis* is very suggestive. An apparently unexplained femoral thrombosis, especially if other thromboses occur elsewhere, in a patient over 50 is sometimes evidence of gastric carcinoma. Thromboses may be so frequent as to constitute the condition described as thrombophlebitis migrans, in which visceral as well as peripheral thromboses occur. Some fever is generally present. It is not at all uncommon for the thrombosis to withdraw attention entirely from any digestive symptoms. I have recently seen three patients at the hospital in which recurring phlebitis was the only symptom complained of; in two of them nothing in the history pointed towards a gastric carcinoma.

Peptic Ulcer.

Anxiety neurosis, neurasthenia, worry, strain, and emotions may cause marked dyspeptic symptoms of purely nervous origin. In such cases the indigestion is generally found, on careful questioning, to follow primary nervous symptoms; the nervousness has not followed the indigestion. At the same time, any fairly long-standing nervous disorder of the stomach may, through the secretory and motor irregularities produced, lead to a true organic catarrh or gastritis. *In practice, therefore,* we are forced to the diagnosis of gastritis and nervous indigestion by a process of exclusion, in which the possibility of ulcer must take first place.

HISTORY.

The typical history of the intermittent pain of peptic ulceration is too well known to require comment. It is important to remember, however, certain points about this history. In the first place it is generally pain and not discomfort that occurs—pain that may be severe and intense, and pain that makes a patient frightened of getting it again. Thus, even in his free periods, the ulcer patient is generally careful of his diet, whereas the chronic appendix or colitis patient, for instance, is apt to forget all restrictions when the pain is not present. Ulcer is certainly the commonest cause of stomach pain, and must be considered in every doubtful case of chronic indigestion, however atypical. The pain is particularly apt to go through to the back, where there may occasionally be found an area of reflex hyperæsthesia close to the spine in the tenth, eleventh, or twelfth intercostal spaces. Ulcer pain does not always show the classical relationship to meals, and Hurst [1] says that in half the cases of gastric ulcer the history is not characteristic.

---

* Based on a lecture delivered at the St. Mary's Hospital Post-graduate Course.

On the other hand, the pain tends to be fairly *constant* in character and site.

CONSTANCY.

Thus the ulcer patient when questioned will usually point out his most tender spot with one or two fingers; other patients, particularly cases of nervous indigestion, will generally use the whole hand and move it over a large area of the upper abdomen. Ulcer patients will nearly always give the same story on different occasions; other patients may give almost completely different accounts of their troubles each time they are questioned.

The age of onset of the symptoms is important and may need very careful questioning—not more than 10 per cent. of ulcers begin before the age of 20, so that a long-lasting indigestion beginning before this age is unlikely to be due to ulcer, and is perhaps most commonly due to a chronic appendicitis, which so often begins with an acute attack in early adult life.

Taking ulcers as a whole, probably between 4 and 5 to 1 occur in males, particularly of course the duodenal ulcers, and a great proportion appear to begin between the age of 30 and 35.

Nausea is not common with ulcer, but is more suggestive of large bowel or gall-bladder disorder. It should always, I think, make us suspect a chronic appendix, cholecystitis, or colitis rather than a lesion of the stomach itself. *Vomiting* is also probably as common in cholecystitis as it is in peptic ulcer. *Water-brash*, on the other hand, is very suggestive of a gastric lesion, and seems particularly common with duodenal ulcer. It is not so often a nervous phenomenon as is generally believed.

It must be remembered that *neurosis* is a highly frequent associate of ulcer, and it is remarkable how much affected are the symptoms of ulcer by worry, anxiety, and fear. Ulcers are not indifferent to psychic states any more than they are indifferent to season and climate. It is very easy to be deceived into thinking that an organic lesion could not possibly be so seriously affected by mental states as patients sometimes say their symptoms are.

One patient whom I saw recently was an extremely neurotic schoolmaster who told me that after interviewing parents about their boys he was always prostrated with intense epigastric pain and profuse vomiting for several hours. He had been invalided from the Army with neurasthenia and had seen numerous boards since and continued to draw a pension. His radiogram shows a very large penetrating gastric ulcer and a probable duodenal ulcer as well.

The pain of ulcer is particularly apt to *wake patients at night*, and pain which awakes patients who have once fallen to sleep must always be regarded as organic unless completely proved otherwise. On the other hand, pain which begins when patients go to bed and prevents them getting to sleep, is often non-organic, since the quiet in bed allows a nervous patient to think more of his symptoms and may enormously exaggerate his condition. Pain which is made worse or prevents a patient *lying on the left side in bed* is also suggestive of duodenal ulcer, and I think this may be due to the weight of the liver dragging on the first part of the duodenum and stretching the ulcer surface, perhaps with adhesions. It is rather rare for ulcer pain to be present first thing in the morning before any food is taken, whilst colon and chronic appendix discomfort is often felt at that time. Ulcer pain is not, as a rule, affected by defæcation, the passage of flatus or the use of purgatives, whilst "bowel" pain often is.

THE CAUSE OF ULCER PAIN.

We are apt to attribute all forms of gastric sensations to acidity, and to speak of hyperacidity as a type of indigestion and a cause of pain in itself. The pain is not, however, closely related to the gastric acidity.

Hardy [2] showed that the administration of hydrochloric acid to ulcer patients, as was suggested as a diagnostic test, gave a variable pain response, often causing no pain and, vice versa, sometimes causing pain though no ulcer was present. The relief of pain following diet or alkalis is probably largely independent of the gastric acidity. I have found, for instance, in ulcer patients that an egg and milk feed with subsequent withdrawal of the stomach contents has revealed almost as high an acidity as that found after giving a strong caffeine test-meal. The two following cases show this clearly. In the first a penetrating ulcer of the lesser curvature was present, and shown without question by X rays. In the second there was a duodenal ulcer.

CASE 1. (*Gastric ulcer.*)

	Free acid. c.cm. N/10 NaOH.	Total acidity. c.cm. N/10 NaOH.	Total chlorides as g. HCl per cent.
Stomach acidity at 1 hr. after—			
(*a*) Caffeine test-meal	34	50	0·320
(*b*) Lenharz feed (℥ vi egg and milk)	25	75	0·380

CASE 2. (*Duodenal ulcer.*)

	Free acid.	Total acidity.	Total chlorides as g. HCl per cent.
Stomach acidity after			
(*a*) Caffeine test-meal (1 hour)	30	48	0·190
(*b*) Lenharz feed (1 hour)	44	90	0·430
(*c*) Lenharz feed (3 hours)	38	64	0·380

It is also certain, as J. F. Venables[7] and A. F. Hurst have shown, that gastric acidity may be higher after the cure of an ulcer by diet and alkalis, when all symptoms have gone, than before treatment when an active ulcer was present. Such terms as hyper- or hypo-acidity can therefore have no real meaning as definite diagnoses of "indigestion." They can be merely variations in function which may often have no relation to the symptomatology. The gastric acid is apt to be blamed for almost all types of indigestion, but chemical analyses of test-meal results can never alone afford a complete diagnosis, and have relatively little value except as confirmatory in duodenal ulcer, carcinoma of the stomach, pernicious anæmia, and gastritis. I am confident that the majority of cases of gastric hypersecretion characterised by pain late after meals—sometimes described as Reichmann's disease—are in fact due to pyloric gastritis, duodenitis, or very often to an actual ulcer.

Just as the highest gastric acidity may be present without symptoms, so may complete absence of hydrochloric acid lead to no indigestion whatever, as is well known. The following case illustrates this well.

The patient was a man of 47, who for 18 months had complained of fatigue, loss of weight, and anorexia, but of no digestive or other symptoms whatever. In view of the anorexia and loss of weight, a radiogram of the alimentary tract had been made, but had shown no abnormality. The stools had also been examined, and a large excess of muscle-fibres found, some eight months previously. Pancreatic insufficiency was suspected, but there had been no improvement with treatment by pancreatin. I thought that the creatorrhœa might be due to a peptic deficiency in the stomach and carried out a test-meal which showed complete achlorhydria and almost total lack of pepsin. Further examination of the blood showed the case to be one of pernicious anæmia, and complete cure resulted with liver treatment and hydrochloric acid. In this case, therefore, there must have been complete failure of gastric digestion—but with normal peristalsis and tone as shown by the barium meal—for many months without any digestive symptoms (except loss of appetite).

Again, typical ulcer pain may be produced by purely mechanical motor irregularities, as is shown by the following case. The patient came to the out-patient department with a story of two and a lf years' "indigestion" in intermittent attacks, using epigastric pain one half to one hour after eals with vomiting which eased the pain, and mporary relief from sodium bicarbonate. Her mptoms were due to a large cystic tumour of the ft kidney deforming the stomach and entirely isappeared when this was removed; they have not curred.

Ulcer pain may persist in spite of apparently areful dieting by the patient himself. On the ther hand, such dieting is usually quite inefficient. rough rule, and one that is of real assistance in iagnosis, is that *pain which is not relieved by two-ourly feeds of egg and milk is almost certainly not due uncomplicated ulcer.* The patient is put to bed or 24 hours and given 5 oz. feeds, every two hours y day and every three hours by night, of the following nixture, which is easily made at home:—

Milk ..	..	2 pints.	Eggs	.. ..	4
Water	..	½ pint.	Sugar	.. ..	℥ii

Almost every case of ulcer is relieved of pain almost mmediately—even when quite considerable pyloric bstruction may be present. The vomiting of ulcer is lso frequently stopped as if by magic. If the pain emains unaltered its cause is either other than ulcer r there is some definite complication, such as dhesions or chronic perforation. In the great majority of cases the patient will be entirely free of symptoms in 24 hours.

The frequency of the feeds rather than their exact composition is probably the most important factor. If there is no change in the pain it is probably due to some non-gastric cause such as chronic appendicitis, colitis, or cholecystitis. With carcinoma of the stomach the pain may persist in spite of this diet, but often it is relieved, which is perhaps unfortunate from the point of view of diagnosis. The following cases illustrates this point

A man, aged 47. Periodic attacks of epigastric pain, about half an hour after food, for nine years. No vomiting. Radiological examination showed a six-hour residue in the stomach with an ulcer almost certainly present on the lesser curvature. Occult blood was present in the stools. He was entirely relieved of symptoms by ulcer diet alone and remained free for four months. Then a return of pain about two hours after meals occurred, even with the diet, and Mr. Z. Cope kindly saw him and explored the abdomen. An inflamed appendix with concretions was found but no ulcer in stomach or duodenum. In view of the X ray and the blood in the stools, I think there can be no doubt that an ulcer had been present on the first occasion and had been cured, whilst the appendix had been entirely quiescent. On the second occasion the appendix had been causing the symptoms (which were somewhat different from those of the previous attacks).

Examination.

It is rare to find a wholly negative result if ulcer is present, even in its quiescent stage. There is almost always a definitely localised point of tenderness on deep pressure, and this point is generally painful on pressure even between the attacks and is often of no greater size than a shilling. Its discovery is a most important piece of evidence. It should be sought by pressure with one finger-tip with equal firmness area by area. Mid-line tenderness is less significant than tenderness to the side, but the site varies considerably, corresponding almost certainly to the ulcer itself, as Morley[3] and others have shown by marking it with a lead circle and radiographing the stomach with a barium meal. The mechanism of its production is a subject of extreme interest, but it is probably caused by peritoneal pressure over the ulcer area. Clinically it is well to define this point precisely when it is found and to mark it with a pencil and check it later on in the examination and, if possible, on one or two subsequent occasions. If due to ulcer it will be found to remain constantly in the same spot, but to sink perhaps an inch downwards in changing from the horizontal to the vertical position. Unlike gall-bladder tenderness it does not move with respiration. This tender spot is of the greatest possible significance in the diagnosis of ulcer, even when history or other evidence is inconclusive. It may be associated with the small area of hyperæsthesia at the back, close to the spine at about the tenth, eleventh, or twelfth ribs on the right side, but reflex bands of hyperæsthesia are very seldom found with ulcer. Mid-line tenderness is often due to pressure over the aorta, and diffuse tenderness in the epigastrium, not localised particularly to one small site, is far less suggestive, and may be present with gastritis or colitis.

Even with the most careful history and clinical examination, it is not always possible to differentiate certainly between ulcer, growth, and cholecystitis or chronic appendicitis. X ray examination will show an ulcer in at least 90 per cent. of cases, and chronic gall-bladder disease in perhaps three-quarters of the cases; a barium meal and enema may afford useful confirmatory evidence of chronic appendicitis; a test-meal can assist in differentiating duodenal ulcer from a chronic atrophic gastritis, and a biliary drainage can help to elucidate gall-bladder disease.

GASTRITIS.

It is, as a rule, only wise to diagnose gastritis, whether primary or secondary to neurosis, after the most thorough process of exclusion. We find, however, by such methods that it is far more frequent than is sometimes believed. In fact, it is probably very common. This has been more clearly shown since the wider use of gastroscopy, and may be still further demonstrated by gastro-photography. In England we, like Sauerbruch, are apt to regard gastroscopy as more dangerous than an exploratory laparotomy, but on the Continent valuable knowledge has been gained by its use, and many writers—like Henning[4] record results in 500 or more cases without ill-effects.

Thus we know, for instance, that gastro-enterostomy is very frequently followed by gastritis, probably due to the regurgitation of bile and intestinal juices into the stomach, which is a commoner cause of persistence of gastric symptoms after this operation than are the adhesions which are more generally diagnosed. Gastritis is almost constant with ulcer and with carcinoma, and follows the use of many chemical substances—e.g., alcohol. Long use of drugs such as digitalis, bromides, and aspirin also produces gastritis.

In general, gastritis is of two types, though it must be admitted that the clinical symptoms and the anatomical changes do not always run parallel. These types may be called the hypertrophic and the atrophic, though the latter may often follow the former. They correspond approximately to the types of hypersthenic and asthenic, or—in terms of secretion only—of hyperacid and hypoacid, though secretion curves do not correspond exactly to the anatomical changes. In the former the mucous membrane is engorged and swollen, often with multiple small erosions and sometimes actually polypoid overgrowths. In the latter the mucous membrane is thin and pale; in both a large amount of mucus is apt to be present.

It is possible that the treatment of gastritis is in some measure a preventive treatment of both ulcer and carcinoma, for an associated gastritis is almost always found. Some workers even regard ulcer as a "complication" of gastritis, and I feel sure that duodenitis without actual ulcer is common. It is most often due to chemical irritation, rather than actual bacteria, although in a number of suspicious cases I have found an abnormal growth of organisms in the duodenal content which, in health, is usually sterile. The gastritis accompanying ulcer is usually situated mainly at the pylorus and often shows small polyps with superficial erosions; the gastritis of congestive heart failure is generalised and shows a very great excess of mucus. Atrophic gastritis is in general less productive of local symptoms than the hypertrophic type.

Alcohol tends at first to cause a hypertrophic gastritis and later an atrophic or "anacid" type.

certainly the commonest cause of stomach pain, and must be considered in every doubtful case of chronic indigestion, however atypical. The pain is particularly apt to go through to the back, where there may occasionally be found an area of reflex hyperæsthesia close to the spine in the tenth, eleventh, or twelfth intercostal spaces. Ulcer pain does not always show the classical relationship to meals, and Hurst[1] *says that in half the cases of gastric ulcer the* history is not characteristic.

On the other hand, the pain tends to be fairly *constant* in character and site.

CONSTANCY.

Thus the ulcer patient when questioned will usually point out his most tender spot with one or two fingers; other patients, particularly cases of nervous indigestion, will generally use the whole hand and move it over a large area of the upper abdomen. Ulcer patients will nearly always give the same story on different occasions; other patients may give almost completely different accounts of their troubles each time they are questioned.

The age of onset of the symptoms is important and may need very careful questioning—not more than 10 per cent. of ulcers begin before the age of 20, so that a long-lasting indigestion beginning before this age is unlikely to be due to ulcer, and is perhaps most commonly due to a chronic appendicitis, which so often begins with an acute attack in early adult life.

Taking ulcers as a whole, probably between 4 and 5 to 1 occur in males, particularly of course the duodenal ulcers, and a great proportion appear to begin between the age of 30 and 35.

Nausea is not common with ulcer, but is more suggestive of large bowel or gall-bladder disorder. It should always, I think, make us suspect a chronic appendix, cholecystitis, or colitis rather than a lesion of the stomach itself. *Vomiting* is also probably as common in cholecystitis as it is in peptic ulcer. *Water-brash*, on the other hand, is very suggestive of a gastric lesion, and seems particularly common with duodenal ulcer. It is not so often a nervous phenomenon as is generally believed.

It must be remembered that *neurosis* is a highly frequent associate of ulcer, and it is remarkable how much affected are the symptoms of ulcer by worry, anxiety, and fear. Ulcers are not indifferent to psychic states any more than they are indifferent to season and climate. It is very easy to be deceived into thinking that an organic lesion could not possibly be so seriously affected by mental states as patients sometimes say their symptoms are.

One patient whom I saw recently was an extremely neurotic schoolmaster who told me that after interviewing parents about their boys he was always prostrated with intense epigastric pain and profuse vomiting for several hours. He had been invalided from the Army with neurasthenia and had seen numerous boards since and continued to draw a pension. His radiogram shows a very large penetrating gastric ulcer and a probable duodenal ulcer as well.

The pain of ulcer is particularly apt to *wake patients at night*, and pain which awakes patients who have once fallen to sleep must always be regarded as organic unless completely proved otherwise. On the other hand, pain which begins when patients go to bed and prevents them getting to sleep, is often non-organic, since the quiet in bed allows a nervous patient to think more of his symptoms and may enormously exaggerate his condition. Pain which is made worse or prevents a patient *lying on the left side in bed* is also suggestive of duodenal ulcer, and I think this may be due to the weight of the liver dragging on the first part of the duodenum and stretching the ulcer surface, perhaps with adhesions. It is rather rare for ulcer pain to be present first thing in the morning before any food is taken, whilst colon and chronic appendix discomfort is often felt at that time. Ulcer pain is not, as a rule, affected by defæcation, the passage of flatus or the use of purgatives, whilst "bowel" pain often is.

THE CAUSE OF ULCER PAIN.

We are apt to attribute all forms of gastric sensations to acidity, and to speak of hyperacidity as a type of indigestion and a cause of pain in itself. The pain is not, however, closely related to the gastric acidity.

Hardy[2] showed that the administration of hydrochloric acid to ulcer patients, as was suggested as a diagnostic test, gave a variable pain response, often causing no pain and, vice versa, sometimes causing pain though no ulcer was present. The relief of pain following diet or alkalis is probably largely independent of the gastric acidity. I have found, for instance, in ulcer patients that an egg and milk feed with subsequent withdrawal of the stomach contents has revealed almost as high an acidity as that found after giving a strong caffeine test-meal. The two following cases show this clearly. In the first a penetrating ulcer of the lesser curvature was present, and shown without question by X rays. In the second there was a duodenal ulcer.

	Free acid.	Total acidity.	Total chlorides as g. HCl per cent.
	c.cm. N/10 NaOH.		
CASE 1. (*Gastric ulcer.*)			
Stomach acidity at 1 hr. after—			
(*a*) Caffeine test-meal	34	50	0·320
(*b*) Lenharz feed (℥ vi egg and milk)	25	75	0·380
CASE 2. (*Duodenal ulcer.*)			
Stomach acidity after			
(*a*) Caffeine test-meal (1 hour)	30	48	0·190
(*b*) Lenharz feed (1 hour)	44	90	0·430
(*c*) Lenharz feed (3 hours)	38	64	0·380

It is also certain, as J. F. Venables[7] and A. F. Hurst have shown, that gastric acidity may be higher after the cure of an ulcer by diet and alkalis, when all symptoms have gone, than before treatment when an active ulcer was present. Such terms as hyper- or hypo-acidity can therefore have no real meaning as definite diagnoses of "indigestion." They can be merely variations in function which may often have no relation to the symptomatology. The gastric acid is apt to be blamed for almost all types of indigestion, but chemical analyses of test-meal results can never alone afford a complete diagnosis, and have relatively little value except as confirmatory in duodenal ulcer, carcinoma of the stomach, pernicious anæmia, and gastritis. I am confident that the majority of cases of gastric hypersecretion characterised by pain late after meals—sometimes described as Reichmann's disease—are in fact due to pyloric gastritis, duodenitis, or very often to an actual ulcer.

Just as the highest gastric acidity may be present without symptoms, so may complete absence of hydrochloric acid lead to no indigestion whatever, as is well known. The following case illustrates this well.

The patient was a man of 47, who for 18 months had complained of fatigue, loss of weight, and anorexia, but of no digestive or other symptoms whatever. In view of the anorexia and loss of weight, a radiogram of the alimentary tract had been made, but had shown no abnormality. The stools had also been examined, and a large excess of muscle fibres found, some eight months previously. Pancreatic insufficiency was suspected, but there had been no improvement with treatment by pancreatin. I thought that the creatorrhœa might be due to a peptic deficiency in the stomach and carried out a test-meal which showed complete achlorhydria and almost total lack of pepsin. Further examination of the blood showed the case to be one of pernicious anæmia, and complete cure resulted with liver treatment and hydrochloric acid. In this case, therefore there must have been complete failure of gastric digestion—but with normal peristalsis and tone as shown by the barium meal—for many months without any digestive symptoms (except loss of appetite).

Again, typical ulcer pain may be produced by purely mechanical motor irregularities, as is shown by the following case. The patient came to the out-patient department with a story of two and a

Tobacco is definitely stimulative to gastric secretion and in some cases appears to excite peristalsis. Gray [6] carried out some experiments on the effects of smoking before a barium meal and before and during a test-meal in 50 cases of duodenal ulcer, and found both an increased acidity and increased peristalsis when tobacco was taken on a fasting stomach. Other experiments have also shown the same effect. Tobacco chewing is a powerful gastric stimulus and can indeed lead to a definite gastritis. I think in a few cases nicotine is a cause of irregular motor activity and spasm in the colon also, so that attacks sometimes described as "abdominal angina" may be produced, as may perhaps (though rarely) pyloric spasm as well. It has unfortunately been shown that the so-called nicotine-free cigarettes or those with varying types of filter have no less nicotine in their smoke than other cigarettes and are therefore probably no less stimulant than others.

Alcohol has important actions upon digestion. Many ulcer patients notice that they are afforded temporary relief by brandy whereas more dilute alcoholic drinks upset them very much. This is due to the fact that a concentration of alcohol in the stomach greater than about 15 per cent. usually causes almost a temporary paralysis with diminution of peristalsis and tone and a checking of secretion. Lesser concentrations have a markedly stimulant action upon both peristalsis and acidity. Undiluted brandy as a treatment for peristaltic unrest is therefore not very different from the mixture which is generally called mist. carminativa, made up of spir. chloroform, spir. cajuput, and the like. These contain about 90 per cent. of alcohol, and the spir. æth. nitrosi is a most convenient way of prescribing alcohol when there are prejudices against ordering it as such.

Tea and coffee are fairly powerful excitants of gastric secretion. A cup of strong coffee contains between one and two grains of caffeine and causes a copious secretion of gastric juice, but weak China tea with milk has a far less stimulant effect. Again, it is disappointing to find that the so-called caffeine-free preparations of coffee show little difference in this activity. Food taken with tea appears experimentally to be less well digested than when taken without.

Rochdale Infirmary and Dispensary.—Jun. H.S. £200.

Royal College of Surgeons of England.—Election of Examiners in Anatomy, &c.

Royal Eye Hospital, St. George's Circus, Southwark, S.E.—Sen. and Jun. H.S. At rate of £150 and £100 respectively.

Royal Free Hospital, Gray's Inn-road, W.C.—Sen. Res. M.O. £150.

Royal Northern Hospital, Holloway, N.—H.S. At rate of £70 Also H.P. At rate of £70.

Ryde, Royal Isle of Wight County Hospital.—Hon. Ophth. Surg.

St. John's Hospital, Lewisham, S.E.—Res. Cas. O. At rate of £100.

St. Olave's Hospital, Lower-road, Rotherhithe, S.E.—Res. H.P. At rate of £80.

Salford, Hope Hospital.—Res. M.O. £400.

Salvation Army, Mothers' Hospital, Lower Clapton-road, Clapton, E.—Jun. Res. M.O. At rate of £60.

Sheffield, Jessop Hospital for Women.—Secretary. £450.

Sheffield Royal Hospital.—H.S. and Res. Anæsthetist. Each at rate of £80.

Southport General Infirmary.—Jun. H.S. £150.

Sutton, Surrey, Sutton and Cheam Hospital.—Res. M.O. At rate of £150.

Watford, Herts, Peace Memorial Hospital.—Res. H.S. At rate of £150.

QUEEN'S HOSPITAL, BIRMINGHAM.—The income last year was £45,109, an increase of £3717; the expenditure was £48,425, a decrease, compared with the previous year, of £2637. The debt is £18,598. The full year's income from private paying patients was £2435. Last year there were 5268 in-patients, 13,753 out-patients, and 16,572 casualties, a considerable reduction in the two latter categories. In-patients cost £2 18*s.* 7¼*d.* per week, as compared with £3 1*s.* 2*d.* in the preceding year; the average cost per bed was £152 15*s.* 11*d.*, as against £159 7*s.* 10*d.* in 1930. Each out-patient cost 4*s.* 3½*d.* in place of the former 5*s.* At the beginning of the year arrangements came into force requiring patients to contribute according to their circumstances; the sum thus received from in-patients was £1664, and from out-patients £947. The amount received from the contributory scheme was only 48 per cent. of the cost of its patients. The stock of radium has been increased from 300 to 340 milligrammes, and has been freely used with encouraging results.

The latter is often found also with bad oral sepsis, poor mastication, and old age. It is frequently accompanied by dirty tongue and a bad taste in the mouth; sometimes by anæmia, acne rosacea, urticaria, arthritis, and "dyspeptic" ulcers in the mouth. The appetite is poor, and thirst is often a marked symptom. The condition is apt to be polysymptomatic, and patients often complain of fatigue, lassitude, headache, and insomnia. Any real epigastric pain is rare. I think some of these cases are due to a constitutionally weak stomach which shows peculiar idiosyncrasies to certain articles of food. In some the condition dates from one of the infective fevers or influenza, in which an endogenous or blood-borne gastritis may have occurred and led to deficient motor activity and hyposecretion.

In the hypertrophic or ulcer type, on the other hand, the appetite is usually good, though the patient may be afraid to eat; the tongue is clean, and the symptoms are essentially abdominal or monosymptomatic.

Treatment.

There are two broad lines of treatment: sedative or stimulant, in other words, a therapy directed towards lessening gastric activity or towards increasing it. The first is required for ulcer patients, for acute and subacute gastritis, and as a palliative treatment in the reflex hyperactivity associated (in the early stages at least) with cholecystitis or appendicitis. The latter is of use for long-standing gastritis, of the toxic or atrophic type; in cases where loss of tone and fatigue is a feature, as in convalescence after the toxic gastritis of fevers; in old age; often in the dyspepsia of tuberculosis and in that found commonly in nervous girls which German authors describe well as a "stomach strike."

In the ulcer régime the diet required is not necessarily fluid but non-stimulating, that is, one which calls forth a minimum of motor as well as secretory activity. Not uncommonly, the diet ordered alternates Bovril with Benger's food, their only common feature being that they are both fluid! The following list is not in any way original, or more than an outline of dietetic treatment. The "egg and milk diet" is that mentioned above; it may be used early in treatment but requires variation according to the stage of healing of the ulcer.

SEDATIVE (ULCER) RÉGIME.

2 pints milk.
½ pint water.
4 eggs.
2 teaspoonfuls sugar.

Five-ounce feeds, 2-hourly by day, 3-hourly at night.

Avoid pickles, curry, spices, vinegar; Acid fruits (especially raw); lemon-juice; fruit with pips, e.g., currants, raisins, figs; peel, e.g., in cake or marmalade; nuts; coarse vegetables, e.g., celery, lettuce; strong meat soups, broths, Bovril, or extracts. Tough meat or high game. Strong tea or coffee. All alcoholic spirits; any alcohol on an empty stomach.

Take especially eggs, egg-dishes, milk and milk foods, custards, junket, jellies. Butter, cream, soft puddings. Plain biscuits, cake, toast, rusks—not new bread. Purées of vegetables and sweet fruits. Fish—not very salted. Meat—not more than once a day, preferably rabbit, lamb, chicken, veal.

Do not go longer than 2 to 2½ hours without a feed.

In addition to diet, alkalis, belladonna, and olive oil are all valuable.

Of the *alkalis*, sodium bicarbonate has had some unkind things said about it but still holds a most important place in treatment. Its actions are essentially: (1) to neutralise acid with (2) the liberation of carbon dioxide; (3) to dissolve mucus; (4) to cause a secondary stimulation of gastric juice; (5) to relax muscle spasm; and probably (6) to relax the pylorus and thus increase the rate of emptying of the stomach.

There is fairly definite evidence that sodium bicarbonate relaxes pyloric spasm, and possibly hypertonicity of the stomach in general. On the other hand, the liberation of carbonic acid gas tends to stimulate peristalsis, and so to hasten stomach emptying time. The third and fourth functions of dissolving mucus and stimulating gastric secretion are clearly valuable in cases of gastritis where mucus coats the stomach and hyposecretion is present, in which case it should be given some 30 minutes before food. As a pure neutraliser of acid, sodium bicarbonate is better replaced by calcium carbonate, magnesium or the citrates, as in the powders I use which I call "Pulv. 1333"—containing one part of sodium bicarbonate and three parts each of precipitated calcium carbonate, the light magnesium oxide and oxycarbonate of bismuth.

Atropine is most valuable as a gastric sedative, for it not only lessens secretion and in large doses actually inhibits it but, by acting on the vagus and the nerve plexuses in the wall of the stomach, it also lessens pyloric spasm as well as gastric tone and peristalsis. Radiological evidence upon the inhibitory action of atropine is not wholly conclusive, but its effect on the secretory curves of test-meals is unquestioned. Dryness of the mouth is a sign that some "drying" of the stomach is occurring. Atropine must be given in good dosage: as tr. belladonna, ♏v. to xv., or as atropine sulphate, gr. 1/150 to 1/200 in a drachm of water.

Olive oil is also a very valuable gastric sedative when taken alone, for it powerfully inhibits both the secretory and motor activity of the stomach. This property has been demonstrated experimentally (Roberts [5]), and is in virtue simply of its being a vegetable fat and is not in any sense specific. It must be given alone, since a combination of fat and protein—as for instance fish fried in oil—has a very different effect. The inhibitory effect of olive oil upon stomach activity is produced after its entrance into the duodenum, and since it has a markedly stimulant action upon biliary secretion it is mildly laxative; its high food value in under-nourished patients is particularly valuable. It is best given before meals and last thing at night in tablespoonful doses. If four doses are given in the day an energy value of about 500 calories is obtained—approximately a quarter of that needed for an average individual.

The strong carminative spirits of the pharmacopœia produce a temporary "paralysis" of the stomach, relaxing motor activity, but are followed by an increased secretion and augmented peristalsis. They should be avoided for anything but temporary use in relieving the severe pain of irregular peristalsis, and should never be ordered for prolonged use as gastric sedatives, particularly in ulceration.

"STIMULANT" TREATMENT.

A varied diet may be given, but milk and fatty foods are generally badly taken. Meat extracts, light wine, tea and coffee are all excitant to the stomach and are useful; some such fluid with meals is often helpful.

Sodium bicarbonate is valuable for freeing mucus and causing a reactionary secretion of gastric juice. It should be ordered before meals with a bitter such as inf. gent. co. which tends to stimulate the psychical secretion and activity of the stomach.

Strychnine has been demonstrated to increase the tone and peristalsis of the stomach, and may be given as liq. strych. ♏ii. to v. or the tr. nux vom. ♏v. to xv. It is best given after meals.

Hydrochloric acid is somewhat disappointing when ordered alone but should be tried in full doses; ♏xxx. to lx. of the dilute acid with or after meals; ʒi. of the glycerin of pepsin should be added to correct a possible ferment deficiency. Strychnine or nux vomica may well be added to this mixture, so that some such prescription as the following may be ordered.

℞	Ac. nitro-hydrochlor. dil.	♏xxx.
	Glycerini pepsini	ʒi.
	Tr. nuc. vom.	♏v.
	Inf. gent. co. ad	℥i.

Such a mixture is often efficacious in the treatment of gastritis when the acute stage is past and the sedative régime has been carried on long enough or, as not infrequently happens, too long.

ADDRESSES AND ORIGINAL ARTICLES

THE RÔLE OF THE HÆMOLYTIC STREPTOCOCCI IN INFECTIVE DISEASE.

BY C. C. OKELL, M.C., M.B. CAMB., M.R.C.P. LOND.,
PROFESSOR OF BACTERIOLOGY IN THE UNIVERSITY OF LONDON, AND BACTERIOLOGIST TO UNIVERSITY COLLEGE HOSPITAL, LONDON.

II.—PROPERTIES OF ERYTHROGENIC (RASH-PRODUCING) TOXIN OF THE STREPTOCOCCI.*

THE properties of the exotoxin of the hæmolytic streptococci which are responsible for the peculiar features of the scarlatinal exanthem and of the Dick test, are so important from the point of view of modern work on the prophylaxis of scarlet fever that no excuse need be offered for considering them in detail. One of the most remarkable properties of this toxin is that when it is suitably diluted and introduced into the human skin it produces a local erythematous patch which appears within a few hours, reaches a maximum within 24 hours and then rapidly fades away leaving at times a desquamating area but never signs of more severe tissue damage. The consistency and appearance of this local patch of erythema so closely resemble those of an actual area of rash in a subject with scarlet fever, that we readily infer that the mechanism of production in the two cases is identical. If this toxin is injected into susceptible human beings in large doses, for example in quantities upwards of a thousand times the dose used in the Dick test, a clinical condition results which resembles a self-limited attack of scarlet fever so closely that it has been described as "the scarlatinal syndrome" or in O'Brien's graphic phrase "miniature scarlet fever." The syndrome comes on a few hours after the injection. The patient often vomits, develops fever, a frequent pulse, a furred tongue, and a generalised rash which in appearance and distribution is indistinguishable from that of scarlet fever. An interesting symptom recorded by a number of observers is soreness of the throat. As in true scarlet fever the rash avoids the face, and the appearance of circumoral pallor has been recorded. A slight albuminuria is common and there may even be transient hæmaturia. Recovery even from large doses is apparently rapid and complete. Toyoda, Moriwaki, and Futagi[1] have recorded a case of the scarlatinal syndrome in which desquamation followed.

No experimental animal has so far been discovered which may be compared with man in susceptibility to this toxin, and thus we have been denied those methods of study which have yielded such a rich harvest in the study of diphtheria. It is doubtful if an intradermic reaction strictly comparable with the Dick reaction can be obtained in any animal other than man. I have attempted to produce Dick reactions in horses, cows, sheep, goats, dogs, cats, ferrets, rabbits, guinea-pigs, rats, mice, and hens but always ineffectually. Even monkeys, at least those of the *rhesus* family, have, in my experience, no skin susceptibility to doses of toxin a hundred times greater than that used for the Dick test in human beings.

Kirkbride and Wheeler[2] claim to have obtained reactions comparable with Dick reactions on the skin of Saanen goats. Their method has been used on a considerable scale at the New York State Department of Health for purposes of standardising streptococcal toxins and antitoxins. Other workers seem to have had very little fortune in confirming these observations of the Albany workers. This may, of course, be due to a failure to secure properly susceptible goats. My own experiences with such goats as I could procure were entirely disappointing. Certain peculiar skin reactions were observed, but these appeared to be unrelated to the specific toxic reaction of the toxin nor could I obtain any results which were capable of numerical interpretation. Ando states that the skin of white pigs will give a Dick reaction; but some dozen pigs, young and old, which I examined failed to give anything resembling a Dick reaction, even when large amounts of toxin were injected. This, I believe, has been the experience of many other workers who have attempted to confirm Ando's observations.

As Parish and I[3] showed, the rabbit, while it gives no skin reaction, is susceptible to large intravenous doses of erythrogenic toxin. In 96 per cent. of cases the animals died within six days, usually within 48 hours. When, however an, adequate dose of streptococcal antitoxin was previously given 87 per cent. of the rabbits survived for longer than six days. In our earlier experiments it needed 5 c.cm. or more of the strongest toxin we could obtain to cause death in this way. The dose employed was at least 5000 times that required to produce a typical Dick reaction, and 50 times that required to produce a generalised scarlatiniform rash, in a susceptible human subject. Hartley[4] and also Pulvertaft[5] with much smaller volumes of concentrated toxin subsequently obtained similar lethal effects and similar specific neutralisation with antitoxin. Hartley produced death with as small an intravenous dose as 0·2 c.cm. of his highly purified preparations. Pulvertaft describes in some detail the gross and minute anatomical changes found in rabbits dying from intravenous injections of toxin, but it is difficult to say if these are in any way characteristic. I was personally unable to satisfy myself that the gross post-mortem changes which were found in such animals gave any reliable information bearing on the essential toxological properties of streptococcal filtrates. Pulvertaft states that the kidneys of these rabbits showed "degeneration of tubules with great congestion in glomeruli and tubules," and that in rabbits which survived more than five days sections showed "cellular casts in the tubules and evidence of round-celled proliferation around the glomeruli."

It has often been surmised that nephritis, a justly feared sequel of scarlet fever and indeed of all streptococcal infection, can be ascribed to the action of the erythrogenic toxin. It has been mentioned that transient albuminuria and even hæmaturia may follow the injection of the sterile toxin into human beings, but it is to be noted that these symptoms accompany the rash at its height and rapidly disappear with the rash, while the characteristic feature of scarlatinal and streptococcal nephritis generally, is that it makes its appearance after a considerable latent period, often after all the acute manifestations of disease have passed away. Two further points may be referred to suggesting that the erythrogenic toxin is not the cause of nephritis. Nephritis may follow in cases of scarlet fever with very slight rash and cases of streptococcal infection with no signs of rash at all, nor has treatment with streptococcal antitoxin ever been clearly proved to influence the subsequent incidence of nephritis.

A little can be learnt about the properties of the erythrogenic toxin from observations of its effects upon the human skin. The toxin, whether injected

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Monday, April 11th.—4.30 P.M., United Services. Annual General Meeting: Election of Officers and Council. Surg.-Commander W. H. Edgar: Scarlet Fever, an Effort in Preventive Medicine.

Tuesday.—8.30 P.M., Psychiatry. Dr. David Forsyth: The Place of Psychology in the Medical Curriculum.

Friday.—5.30 P.M., Physical Medicine. Sir Robert Jones: Manipulation as a Therapeutic Measure. Radiology. There will be no Meeting of the Section on this day. 8 P.M., Physical Medicine and Radiology. 8.15 P.M., Obstetrics and Gynæcology. Short Communications. Mr. D. H. MacLeod: Two Cases of Struma Ovarii. Mr. Victor Bonney: Two Cases of Implantation Endometriomata. Papers: Prof. Leith Murray: Ectopic Gestation as seen by the Gynæcologist; An Analytical Study of 146 Cases. Dr. A. A. Gemmell and Prof. Leith Murray: Two Cases of Simultaneous Intra- and Extra-uterine Pregnancy.

HARVEIAN SOCIETY.

Thursday, April 14th.—4.30 P.M., Clinical Meeting at King's College Hospital.

PADDINGTON MEDICAL SOCIETY.

Tuesday, April 12th.—9 P.M. (at the Great Western Royal Hotel, Paddington, W.), Debate on a State Medical Service, to be opened by Mr. Somerville Hastings and Sir Ernest Graham Little, M.P. Non-members invited.

MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY, 11, Chandos-street, Cavendish-square, W.

Thursday, April 14th.—8.30 P.M., Dr. H. C. Squires: A Novice's Impressions of the Theory and Practice of Individual Psychology.

SOUTH-WEST LONDON MEDICAL SOCIETY, Bolingbroke Hospital, Wandsworth Common.

Wednesday, April 13th.—9 P.M., Mr. C. Rowntree: Common Diseases of the Mouth.

SOCIETY FOR THE STUDY OF INEBRIETY.

Tuesday, April 12th.—4 P.M. (in the Rooms of the Medical Society of London, 11, Chandos-street, W.), Annual Meeting. Dr. J. D. Rolleston will open a discussion on the Cigarette Habit.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Friday, April 15th.—5 P.M., Dr. R. Fortescue Fox and Dr. G. R. Bruce: The Provision of Medical Baths by Local Authorities.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, April 11th, to Saturday, April 16th.—Queen's Hospital for Children, Hackney-road, E. Post-graduate Course in Diseases of Children. All day.—London Lock Hospital, Dean-street, W. Post-graduate Course in Venereal Disease. Every afternoon. (The above Courses are open only to Members.)—Children's Heart Hospital, West Wickham, Kent. Sat., 10.30 A.M. to 12 no [illegible] y Dr. Berr [illegible] and Hea [illegible] from the [illegible]

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith-road, W.6.

Monday, April 11th.—10 A.M. to 1 P.M., Gynæcological Ward, Surgical Wards, Genito-Urinary Operations, Skin Department. 2 to 4 P.M., Operations, Surgical Wards. Medical, Surgical, Gynæcological, and Eye Out-patients. 4.15 P.M. (Lecture) Sir Henry Simson: The Management of Pregnancy and Labour.

Tuesday.—10 A.M. to 1 P.M., Medical Wards, Surgical Demonstration, Throat Operations, Dental Department. 2 P.M. to 4 P.M., Operations, Medical, Surgical, and Throat Out-patients. 4.15 P.M. (Lecture): Mr. Tyrrell Gray: Visceroptosis in Relation to other Diseases.

Wednesday.—10 A.M. to 1 P.M., Medical Wards, Children's Medical Out-patients, 2 P.M. to 4 P.M., Gynæcological Operations, Medical, Surgical, and Eye Out-patients. 4.45 P.M., [illegible]

Thursday.—1 [illegible] Fracture [illegible] Medical, [illegible] patients. 4.15 P.M. (Lecture): Dr. Scott Pinchin: Diseases of the Bronchi.

Friday.—10 A.M. to 1 P.M., Medical Wards, Skin Out-patients, Dental Department. 12 noon, Medical Lecture. 2 P.M. to 4 P.M., Operations, Medical, Surgical, and Throat Out-patients. 4.15 P.M. (Lecture): Mr. Alex. Roche: Indications f [illegible]

Saturday.—9 A.M. to 1 P.M., Throa [illegible] Wards, Surgical and Children's [illegible] The lectures at 4.15 P.M., on [illegible] Thursdays, and Fridays are ope [illegible] titioners without fee.

LONDON JEWISH HOSPITAL, Stepney Green, E.

Thursday, April 14th.—4.15 P.M. Dr. M. Schwartzman: X Ray Demonstration.

ST. PETER'S HOSPITAL, Henrietta-street, Covent Garden, W.C.

Wednesday, April 13th.—3 P.M., Mr. J. A. Andrews: Pre-operative Treatment of Enlarged Prostate.

ST. MARK'S HOSPITAL, City-road, E.C.

Thursday, April 14th.—4.30 P.M., Dr. J. B. Alexander: The Relationship of Tuberculosis to Anal Fistulæ.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL Gray's Inn-road, W.C.

Friday, April 15th.—4 P.M., Mr. A. Ryland: Temporal Bone. (Lantern lecture.)

SALFORD ROYAL HOSPITAL.

Thursday, April 14th.—Dr. A. G. Bryce: Demonstration of Surgical Cases.

ROYAL SAMARITAN HOSPITAL FOR WOMEN, Glasgow.

Wednesday, April 13th.—4.15 P.M., Dr. John Gardner: *Gynæcological Cases.*

ANCOATS HOSPITAL, Manchester.

Thursday, April 14th.—4.15 P.M., Dr. G. J. Langley: Treatment of Cardiac Vomiting.

MANCHESTER ROYAL INFIRMARY.

Tuesday, April 12th.—4.15 P.M., Mr. P. R. Wrigley: Diagnosis and Treatment of Carcinoma of the Colon.

Friday.—4.15 P.M., Mr. A. H. Southam: Demonstration of Surgical Cases.

Appointments

Tame, R. G., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Cranborne District of the County of Dorset.

Births, Marriages, and Deaths

BIRTHS.

Dix.—On April 3rd, 1932, at a nursing home, to the wife o Victor W. Dix, F.R.C.S.—a son.

Montgomery.—On March 29th, at South Park Hill-road, South Croydon, the wife of Stephen K. Montgomery, M.D., of a son.

Nourse.—On April 3rd, the wife of H. E. Nourse, M.R.C.P., of Grange-road, Cambridge, of a son.

MARRIAGES.

Blaikley—Johnson.—On April 2nd, at St. Stephen's Church Guernsey, John Barnard Blaikley, F.R.C.S., to Vivie Maude, younger daughter of Edward Odlum Johnson, O.B.E., I.S.O., formerly of Sierra Leone.

Smith—Fowler.—On April 2nd, at St. Peter's, Eaton-square, George Francis Rawdon Smith, M.D., of Liverpool, to Ethel May Fowler, only child of the late James Stewart Fowler, M.D., of Edinburgh.

Stevenson—Lang.—On March 31st, at Frimley Parish Church, Surrey, Douglas Stuart Stevenson, M.B.E., M.B., Ch.B., to Mary Edith, younger daughter of the late Captain E. L. Lang, Royal Navy, and the late Mrs. Lang, of Craig Bittern, by Dalbeattie.

Stewart—Greenwood.—On April 4th, F. M. Stewart, M.B., Ch.B. Edin., Littlemore, near Oxford, to Susan Helen Greenwood.

DEATHS.

Mooney.—On March 26th, Alexander Patrick Mooney, M.D. J.P., M.B.E., of Preston, Lancs., aged 71.

Nelis.—On March 29th, at The [illegible] Devon William Francis Nelis, M.I [illegible] of the Newport Ment [illegible]

Robertson.—On March 2 [illegible] Edinburgh, George [illegible] F.R.C.P. Edin., F.F [illegible] Psychiatry in the U [illegible] Superintendent of t [illegible] Mental and Nervous Disorders.

Smith.—On March 31st, James Edmund Smith, M.R.C.S. L.R.C.P., of Whitehead's-grove, Chelsea, S.W.

Somerville.—On March 30th, at Harrold, Bedford, Henr Inkerman Somerville, L.R.C.P., M.R.C.S., B.Sc. Lond. aged 76.

Urquhart.—On March 28th, at Cairo, Egypt, Alexander Lewi Urquhart, O.B.E., late Major, R.A.M.C., Professor o Pathology at the University of Cairo.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Fire at a Hospital.—Fire broke out last wee in a ward of the Infectious Diseases Hospital at Oxford. Th ward had been redecorated, and shortly after fires had bee lighted and three patients moved in beams near a chimne were found to be on fire. The flames spread rapidly, bu the patients were safely removed, and the fire brigad speedily put an end to the outbreak. A few of the helper were slightly injured.

we only found the Dick reaction with 1/2000 greater than that with 1/4000 in 72 per cent. of a large group of individuals. We were thus only able to distinguish a toxin dilution from one twice its strength or half its strength on a strictly statistical basis. On a few subjects the chance of a correct comparison was little better than 1 in 2.

Nor does any alternative method of titration present itself which gives greater accuracy. Whether we compare toxins on normal individuals, early cases of scarlet fever, scarlet fever convalescents, or by intravenous injection of the rabbit, whether we assess the values by comparison of individual Dick reactions on the same patient or on different patients, or whether we rely on comparisons of the Dick-positive rate of a large group of individuals, normal or convalescent, we have not been able in our own work to do more than distinguish a toxin amount x from an amount $2x$.

Similarly, in an investigation into the limits of accuracy of the titration of streptococcal antitoxin we were unable by skin neutralisation tests, Schultz-Charlton tests, or passive immunity results on human beings, or by the rabbit method, to do more than distinguish an antitoxin amount x from one $2x$. Compare this with the beautiful precision achieved in titrating the analogous diphtherial product, in which 1/20 differences of antitoxin strength can be readily detected by intradermic tests on guinea-pigs and the presence of so small a quantity as 1–20,000 unit of antitoxin in a 0·1 c.cm. volume be detected (Glenny) under good experimental conditions.

The failure to discover a metrical method providing a degree of accuracy adequate for the purposes of investigation and the confusion that has resulted therefrom illustrate only too well the truth of Clerk Maxwell's remark that "the most important step in the progress of every science is the measurement of quantities." It is this failure in quantitative methods, combined with a very prevalent lack of appreciation of the serious nature of the impasse reached, which has perhaps more than anything else kept our knowledge of the Dick test in relationship to human immunity so confused and unsatisfactory. It must be recognised that to the present moment it has proved impossible to match two successive batches of toxin for the Dick test so closely that they will give approximately the same results on a large series of human beings. It is fortunate that in Great Britain nearly all the routine tests recorded since the test was introduced in 1924 have been done with one batch of toxin which has been under constant supervision as regards stability and other properties. This means that in England at least, the Dick tests which are recorded are numerically comparable. But it is difficult to link up the work done elsewhere with that done in our own country, and much of the experience accumulated on the Dick test is thus not negotiable between nation and nation nor in many cases between individual and individual.

FURTHER DIFFICULTIES.

In addition to the difficulties and uncertainties of the test which depend upon difficulties of titration of toxin and antitoxin, there are other directions in which the Dick test falls short of the Schick test as a weapon in the control of disease. It must be admitted that many careful observers have met with scarlet fever in clearly Dick-negative individuals. Cases of this kind, in which the prediction of immunity as judged by skin-test observations is falsified, occur of course also in connexion with diphtheria, but so far as one can say very much less frequently. On the other hand the presence of a Dick-positive reaction does not appear to be a clear indication of susceptibility to scarlet fever. It is true that those obviously immune to the disease, such as the more seasoned physicians and nursing attendants at fever hospitals, are almost invariably Dick-negative whether they are known to have had scarlet fever or not, but as we pointed out some years ago,[13] a large proportion of persons who have had a history of scarlet fever in early life are still positive to the Dick test read in the ordinary way (13, or 65 per cent. in one group of 20). In some cases the reaction shows a diminution in size but in others it is frankly positive. Yet clinical experience indicates how rarely scarlet fever is met with in persons with a history of previous infection and one can hardly suppose that more than a fraction of these Dick-positive persons would in reality contract the disease if exposed to it.

Most observers have failed to record anything approaching a hundred per cent. Dick-positive rate during the first one or two days of the disease, and we cannot explain this away by assuming that patients may change from a positive to a negative reaction in this time. All our knowledge suggests that a distinctly longer interval must elapse before we can expect the development of immunity to show itself in cases of scarlet fever.

One also meets with an unexpected number of Dick-positive individuals during convalescence from scarlet fever even when there is little doubt as to the correctness of the diagnosis. It one series of 119 cases we found as many as 22 Dick-positive between the third and the twelfth week after onset, 12 being apparently fully positive. In 14 at least out of the 22 cases no reason whatever could be found to doubt the clinical diagnosis.

That patients may pass through a definite attack of scarlet fever yet remain Dick-positive may have a bearing on the subject of relapses. One at least of those mentioned who had passed through a clinically definite attack and had remained Dick-positive developed a second and typical attack a day after the Dick test had been read. The alternative explanation of relapses—that they are due to a second invasion with a streptococcus of a different agglutination group from the first—is inadmissible since, as I have already pointed out, there is no evidence that the different serological groups of streptococci produce more than one erythrogenic toxin, and if a negative Dick test is in reality a useful indication of true immunity there is no reason against inferring that a Dick-negative convalescent should not be as immune to the new as to the original invader. Apart from other evidence, the rareness of second attacks of scarlet fever supports strongly the view that the erythrogenic toxins of the streptococci obtained from cases of the disease are identical.

These points illustrate, I think, sufficiently clearly the intrinsic difficulty of estimating the value of the Dick test as a practical measure in preventive medicine. To say that the discrepancies that one meets with depend upon a bad choice of the test dose of toxin simply emphasises the fundamental difficulty caused by there being no true standard of measurement in these matters; one observer can only argue with another when both have used the same toxin in the same dilution. Even then the discrepancies remain.

PSEUDO-REACTIONS.

Ando and Kurauchi[14] and Toyoda have attempted to account for the admitted difficulties in Dick-testing by suggesting that an adventitious nucleoprotein derived from the bacterial bodies is present in the crude erythrogenic toxin and that discrepancies may disappear if a purified toxin is used. They intradermically as in the Dick test or pricked into the skin as in Lewis's[6, 7] technique, produces in susceptible persons a patch of bright scarlatiniform erythema. Serious damage of the skin does not take place even when very large doses are injected. Large doses may produce extensive areas of reaction and even a more intense erythema, but, except for occasional minute petechiæ which seem to be due to the bursting of over-distended vessels, nothing resembling a tissue necrosis is to be observed. It is not in fact a pyogenic toxin.

Little can be said of the nature of the erythematous reaction. It is at least different from the reaction to trauma or to the histamine-like effect described fully by Thomas Lewis. It is perhaps most analogous with the delayed erythematous reaction produced by exposure to a moderate dose of light as has been described by Lewis and Grant. We do not in fact know whether or not the cutaneous manifestations are in the main due to a direct action of the toxin on the vessels or indirectly through the nervous system.

A SINGLE ERYTHROGENIC TOXIN ?

A majority of hæmolytic streptococci from acute human disease produce one and the same erythrogenic toxin ; this conclusion follows from the observations on human beings by McLachlan,[8] J. Smith,[9] Kirkbride and Wheeler,[10] Toyoda[1] and his colleagues and ourselves. It also obtains support from experiments on animals. Not only do hæmolytic streptococci from diverse forms of disease produce a similar septicæmia in rabbits but so far as Parish and I[3] could ascertain the lethal effect of different streptococci introduced intravenously could be specifically modified by the use of antitoxin prepared against filtrates from puerperal fever, erysipelas, and cellulitis, as well as scarlet fever strains. We recorded similar cross-neutralisation using filtrates (toxins) for the intravenous injection.

It would take too long to review in full the evidence in favour of there being one type of erythrogenic toxin among the hæmolytic streptococci. Some of the claims made in favour of a plurality of toxins are based on quantitative differences in effects and as I shall endeavour to show later, quantitative ideas must be applied to the study of this type of toxin with a due appreciation of their limitations. The immunological identification of toxins is, however, a sufficiently precise science and it seems to me a reasonable attitude to be chary of mere statements on the subject. If there are in fact other streptococcal toxins it should be possible to hand them over in bottles for impartial study. A toxin which cannot stand this acid test hardly calls for recognition.

From this general statement we may have possibly to exclude the hæmolytic *Streptococcus epidemicus* which has of late been found repeatedly in connexion with milk-borne epidemics of sore-throat, particularly in America. Except in its greater tendency to produce capsulated forms this streptococcus differs little from the typical pyogenic streptococci, of which it may be merely a colony variant, but Pilot and Dreyer[11] have recently claimed that it forms an erythrogenic toxin similar in toxic properties to that of scarlet fever strains but immunologically distinct from it. Nor is it improbable that with the advance of research further erythrogenic toxins with special immunological features will be separated out from streptococci. But so far as current knowledge goes, with the possible exception of the case of *S. epidemicus*, it may be stated that only one immunologically distinct erythrogenic toxin has been identified in connexion with the hæmolytic streptococci.† In my experience very few strains of hæmolytic streptococci, whatever their source, are met with that fail to produce this toxin to a greater or less extent under laboratory conditions. It seems to be the rule that strains from scarlet fever produce the toxin much more actively than strains from ordinary streptococcal conditions without rash, but to this rule there are many exceptions. Strains from typical scarlet fever are sufficiently commonly found that produce toxin poorly in the laboratory and I have met with strains from ordinary streptococcal angina and from erysipelas which have in-vitro toxigenic powers comparable to typical scarlet fever strains.

The production of the erythrogenic exotoxin appears to be a direct function of the growth and multiplication of the streptococci. Observations made by Watson and myself in 1924 (unpublished) indicate that the curve of toxin production shown by Dochez's streptococcus follows closely the curve of growth of the cocci during the logarithmic phase. On Hartley and Watson's modification of Douglas's trypsinised broth, maximum growth was reached within 16 to 24 hours, by which time a maximum of toxin is reached. If the pH of the broth at the time of inoculation is pH8 at the end of the growth phase it reaches pH5 to 6 and thus the pH change can be used for judging the best time to harvest the toxin.

Immunological Properties of the Erythrogenic Toxin.

It is no exaggeration to say that the discovery by G. F. and G. H. Dick in 1924 of a skin test which was closely correlated with immunity to scarlet fever inaugurated a new era in the study of streptococcal disease. The new test looked as if it would at once emulate the Schick test in its theoretical interest and in its practical application. The codified knowledge which had accumulated in connexion with the Schick test seemed to be immediately applicable to the Dick test. These hopes have been, however, to a large extent disappointed. Difficulties, both practical and theoretical, were almost at once met with which indicated that our understanding of this test and its application was on a much more insecure basis than our understanding of the analogous Schick test. This unsatisfactory position is, to a great extent, due to the absence of a suitable experimental animal for the purposes of laboratory investigation. To an almost equal extent it is due to certain peculiar features of the erythrogenic toxin. The contribution of the Schick test to the elucidation of the immunological problems of diphtheria is due to the fact that the test lends itself to quantitative study. Its value in this respect depends in turn on the great precision with which diphtheria toxin and antitoxin can be measured on small laboratory animals. By Römer's intradermal technique as perfected by Glenny[12] it is possible to detect as small a quantity of diphtheria toxin as one-thousandth of the minimum lethal dose (M.L.D.) for a guinea-pig and toxins can be compared with a percentage error of about 5 per cent. Now it has proved impossible to measure streptococcal toxin in the same manner even in susceptible human patients.

If, for example, one attempts to compare the effects of a toxin dilution of a certain strength with those of a dilution a quarter of that strength, extremely discordant results may be obtained if only a small number of susceptible subjects are used. Parish and I found that using 0·2 *c.cm.* of two dilutions of one toxin (1/2000 and 1/4000) in the Dick test sitiveness was proved not to be due to the presence antitoxin derived from the mother for not only d many Dick-positive mothers children who were ck-negative, but the Dick-negative children had no tectable antitoxin in their blood. As the child ows older, skin-sensitiveness to the toxin gradually velops, so that at the end of the first year of life arly all children have become sensitive and give positive Dick reaction. Cooke connects the development of sensitiveness with the common presence of emolytic streptococci in the respiratory passages of fants.

---

† Williams and Gurley (Jour. Bact., 1932 xxiii 241) have,

In support of this view he states that infants more or less olated from each other developed sensitiveness more slowly an those grouped together in residential institutions. In a oup of 100 children under ordinary domestic conditions ly one was found to harbour hæmolytic streptococci, while a group of 100 who were in a foundling home 64 harboured ch streptococci. Sensitiveness to toxin was found to evelop earlier and more markedly in the latter group.

e also claims that in one instance an insensitive hild was made sensitive by the injection of serum rom a very sensitive person, in other words, the ensitiveness could be passively acquired. These bservations Cooke has used to support the theory hat the acquisition of sensitiveness to streptococcal oxin is an anaphylactic type of phenomenon, theory which from time to time has had many dherents in the past and is indeed a component n the outlook of many modern workers on scarlet ever.

Dochez and Sherman,[20] on the basis partly of human bservation and partly on animal experiments, come to very much the same view. They found that while guinea-pigs are normally insensitive to intracutaneous injections of filtrates from toxigenic streptococci, the animals could to some extent be made sensitive by previous injection with cultures and filtrates. They have even described a generalised erythema following the injection of a sensitised guinea-pig.

In our own experiments we were quite unsuccessful in sensitising guinea-pigs and rabbits to toxin as such. It was comparatively easy to reproduce Dochez and Sherman's phenomenon in guinea-pigs, but we found that in "sensitised" animals, skin reactions could be elicited not only by the injection of active scarlatinal toxin but also with filtrates heated to 100° C. for three hours, an exposure which we have found destroys all potency in a toxin as judged by reactions in Dick-positive human beings. Nor could these reactions be prevented by mixing the toxin with potent antitoxin. The sensitisation was evidently against some streptococcal protein not against the toxin as such. Mackie and McLachlan[21] have come to a similar conclusion as to the nature of the Dochez-Sherman phenomenon.

The so-called anaphylactic or "allergic" conception of scarlet fever has to my mind little to recommend it. The phenomenon presented by scarlet fever has no sufficiently close resemblance to properly defined anaphylactic reactions or to such peculiar reactions as the tuberculin reaction to provide a basis for a useful analogy. Allergy is a term used too often in ætiological arguments to give a touch of mystification to ignorance. So far as current knowledge goes we cannot readily identify "immunisation" with "desensitisation," nor anaphylactic antibodies with antitoxins.

The skin insusceptibility of infants to streptococcal toxin is by no means an isolated phenomenon in the immunology of toxins. It is for example well known that a majority of children under six months of age are Schick-negative and that only between the ages of 4 to 8 months do they become susceptible to the Schick dose of toxin. This has been ascribed to the passive transference of diphtheria antitoxin from mother to child via the placenta, which is known to take place from the work of Gröer and Kassowitz.[22] The explanation of the rather long duration of the passive immunity thus conferred was that the antitoxin was in the form of homologous or maternal protein and would be much longer retained than it would have been had it been conferred in the form of a heterologous protein such as antitoxin derived from the horse. It is true that passive immunity is conferred to the child by those mothers who have antitoxin in their blood, but it by no means follows that such small quantities of antitoxin as are found in new-born children would last sufficiently long to account for the large number of children in the third and fourth month who are still Schick-negative. Glenny, Maizells, and myself have recently taken up the investigation of this subject and we have found that out of 37 children between the ages of 3 weeks and 6 months only two were Schick-positive, 29 out of the 35 Schick-negative children had less than 1/500 unit of antitoxin per c.cm. of blood and 21 had 1/1000 unit or less. The failure of small children to react to the Schick test is not therefore necessarily associated with the presence of circulating antitoxin. The problem of insusceptibility of infants to the Dick test has thus its parallel in the Schick test. We have not yet data which allow us to decide whether or not this non-reactivity of the skin is associated with a general insusceptibility to the toxin, but epidemiological experience strongly suggests that very small children show a remarkable immunity to both diphtherial and scarlatinal infection. If this is really so it is a strange provision of nature that after birth we actually *develop* a susceptibility to diphtheria and scarlet fever. It would be premature to attempt to explain how children acquire sensitiveness to bacteria in this way. Hæmolytic streptococci are certainly sufficiently widespread that their presence could be invoked to explain a specifically acquired sensitiveness to them and their toxin, but our experience does not allow us to admit that toxigenic diphtheria bacilli are similarly ubiquitous and could account for the universal acquirement of sensitiveness to diphtheria toxin during those first and usually sheltered months of infant life.

In this connexion I might refer to some observations of Parish and myself[23] on streptococcal infections in rabbits. We found that young rabbits are significantly less sensitive to intravenous injections of living hæmolytic streptococci and also to their toxic filtrates than rabbits of greater age, and we were unable to increase their sensitiveness by artificial methods.

The problem of the acquirement of susceptibility to certain infecting agents and their toxins is a very interesting one and calls for more thorough investigation, but lightly to accept explanations of scarlet fever on the ground of "allergy" would be to constitute an ill-advised revolutionary change in our immunological ideas. It is perhaps simpler to restate the problem in Erhlich's terms and consider that at an early stage of life certain "receptors" have not yet been developed; this is not only indicated by the fact that the cells cannot be poisoned but also, if we accept Grasset's[24] observations on the failure of chicks in the egg to develop antibodies to diphtheria toxoid, by their lack of antigenic response as well.

Desquamation.

Before leaving the subject of the erythrogenic toxin of the streptococci there is one problem which is, I think, worth referring to. It is a time-honoured clinical custom to accept the appearance of desquamation as clinching the diagnosis in a difficult case of scarlet fever. I have already mentioned that Toyoda records desquamation as following an overdose of the sterile erythrogenic toxin of the streptococcus and indeed it is difficult to avoid the would, in fact, ascribe much of the difficulty to the occurrence of "pseudo-reactions." The importance of pseudo-reactions in interpreting the findings of the Dick test seems to be exaggerated by Ando. The toxins which have been extensively used in recent years only give rise to pseudo-reactions, in the dilution used, in very exceptional cases. In many hundreds of consecutive Dick tests I have failed to meet with any reaction that I could ascribe to the "heat stable" substances to which Ando applies the rather misleading term "endotoxin." That this is common experience is indicated by the fact that many workers have given up the use of a control injection in practical routine.

Compared with the exotoxins of the diphtheria, tetanus, and gas-gangrene bacilli the erythrogenic toxin of the hæmolytic streptococcus is a remarkably stable reagent. Its keeping properties and its stability to heat are so superior to those of the classical toxins that it has often been suggested that it should not lightly be classed with them. Dilutions of a toxin in saline are practically uninfluenced by heating for ten minutes at 75° C., an exposure which almost always completely inactivates diluted diphtheria toxin. It is now generally recognised that in order to destroy all the toxin in a 1/1000 dilution of a typical active filtrate it is necessary to heat it for at least two hours at 95–100° C., an exposure which of course makes it difficult to assess the significance of pseudo-reactions, since any coagulable protein must be severely damaged by such treatment.

While the stability of the toxin has been a very helpful property in the issue of materials for the Dick test, in one direction it has caused difficulty. In the method of active immunisation against scarlet fever by means of the toxin we have to face the fact that to protect children against a disease which at the present time causes little terror we have to employ a troublesome and often disturbing method of immunisation. To avoid all untoward effects of immunisation it is necessary to advance slowly and cautiously from dose to dose of toxin. If, on the other hand, a rapid immunity is required from a practical number of injections it appears impossible to avoid a certain percentage of local and systemic reactions and, speaking generally, the results have not been considered by most hygienists to be worth the cost. There is in fact no comparison between diphtheria and scarlet fever prophylaxis in the ease and safety of the immunising process or the certainty of the practical result.

A SCARLET FEVER TOXOID ?

Much of the confidence which has been put in the safety of immunisation against diphtheria in recent years comes from the use of toxoid in one form or another as the prophylactic agent, and the question arises whether a similar modification of scarlet fever toxin exists. By a toxoid we mean a derivative of a toxin which, while it preserves the specific antigenicity and combining power of the original toxin, lacks its toxic properties. Ehrlich recognised the existence of material with such properties in aged toxins, but the discovery of Löwenstein that the classical exotoxins could be simply converted into toxoid by exposure to formalin made it possible to control the production of toxoid at will. Ramon's discovery of an in-vitro method of measuring toxoid (and thus indirectly antigenic power) made it still further possible to extend the use of toxoid in practical immunisation against the common exotoxins.

It is unnecessary to say that following the introduction of toxin immunisation against scarlet fever, efforts were made by many workers to produce a formol-toxoid from the active toxin. It was found that the remarkable stability of the toxin against heat was paralleled by its stability when treated with formalin. When 0·3 per cent. formalin, the amount usually used for "toxoiding" diphtheria toxin, was added to the streptococcal toxin, little change was noted even when kept for many weeks at 37° C. By increasing the amount of formalin to 0·5 per cent. or more and keeping for several weeks, a considerable loss of toxicity took place.

It is doubtful if any formal proof exists that a change from streptococcal toxin to toxoid takes place under these conditions of detoxication, and so far as I can ascertain immunisation has never been obtained by such material unless at least 1/100 of the original toxic activity is retained.

Veldee[15] obtained a 96·9 per cent. Dick-negative rate when immunising Dick-positive adults and children with a formalinised toxin retaining only a 1/100 of its original toxicity as estimated by skin tests. He gave three to five doses of the material usually with an interval of 21 days between doses. The total quantity of active toxin given was less than the equivalent of 2000 skin test doses, yet it is not impossible that so small an amount of active toxin given with such long intervals between doses might account for the resulting immunity.

It also appears from Toyoda, Moriwaki, and Futagi's[1] observations on "toxoid" immunisation that toxic and antigenic power disappear pari passu in the formalinisation process. A significant immunity was only obtained when the material retained some degree of toxicity and the best all-round results were obtained with a preparation that produced generalised rashes in 1·3 per cent. of individuals immunised.

Other methods of study have equally given very uncertain indications as to the existence of a true toxoid to the streptococcal toxin. I have myself on many occasions attempted to utilise the flocculation test for the examination of this question and always without results. Eagles[16] was similarly unable to convince himself that such a test has any value, though Ramon[17] and his colleagues have claimed that the combining power of streptococcal toxin and antitoxin can be estimated in this way. Certain phenomena met with in the study of neutralising effects in human beings, particularly in those individuals who have a certain degree of immunity, might be interpreted as depending upon the presence of a combining as apart from a toxic element, but the difficulty of metrical precision in the estimations of such effects makes it unsafe to force their interpretation. It thus seems that we must prove the existence of a "scarlet fever toxoid" before discussing its use.

In dwelling on the disadvantages and difficulties I do not wish to imply that the methods of Dick-testing and active immunisation against scarlet fever have not an important place in preventive medicine. Already the incidence of scarlet fever among the nursing staffs of an increasing number of isolation hospitals has been reduced to negligible figures and the recent work of Stallybrass[18] indicates that practical results may even be obtained in children's institutions.

The "Allergic" Conception of Scarlet Fever.

A point of great biological interest which has arisen in the study of the Dick test is the curious lack of reactivity to the test observed in children during the first few months of life. With the exception of a series of interesting papers by Jean Cooke[19] there has been little comprehensive work carried out on this subject. Cooke showed that the majority of new-born children are not skin-sensitive to considerable amounts of the erythrogenic toxin. The lack of view has been most ably expounded by Trotter. I shall, however, put forward certain objections to the acceptance of the hypothesis that increased intracranial pressure is the essential cause of the clinical state we are considering.

In the first place the clinical picture of traumatic stupor is not strictly comparable with that encountered in patients whose cerebral symptoms are known to depend upon increased pressure. In a case of hydrocephalus, for instance, caused by a subtentorial tumour, the mental state is, as a rule, that of stupor with apathy. There is usually none of that irritability, restlessness, and confusional excitement which characterise the state which I have called traumatic stupor and which have earned for it such descriptive titles as "cerebral irritation" or "traumatic delirium." Indeed, if we look for comparable clinical states, we shall find them in such conditions as infective or toxic delirium, or in encephalitis, rather than in simple states of increased intracranial pressure.

The second important objection is that, although in the majority of cases of traumatic stupor the pressure of the cerebro-spinal fluid is raised, I have found no correlation between the degree of pressure and the severity of the clinical state, and in some instances of severe traumatic stupor have found the pressure little raised or even normal. For example:—

A man, aged 66, was knocked down by a car on the night of June 30th, 1929, and admitted to hospital late the same night. On admission he was in a state of stupor. I saw him on July 2nd, 36 hours after the injury. There were abrasions of face and scalp, but no evidence of fractured skull. He was stuporose and restless, needing to be restrained at times from getting out of bed. I could find no signs of any focal lesion of the brain. Both plantar responses were flexor. The cerebro-spinal fluid showed a pressure of 120 mm. of water, and was evenly blood-stained. During the subsequent ten days he remained so confused and restless as to need a male attendant. He gradually recovered, and when last seen, five months later, was quite well save for occasional giddiness on turning his head quickly.

Comparable observations are:—

Male, 52. Nine days after injury: stupor continuous since accident; cerebro-spinal fluid xanthochromic; pressure 130 mm. water.

Female, 46. Five days after injury: restless stupor; cerebro-spinal fluid slightly blood-stained; pressure 150 mm. water.

Male, 48. Two days after injury: stuporose; cerebro-spinal fluid slightly yellow; pressure 110 mm. water.

Male, 16. Three days after injury: semi-conscious and resistive; cerebro-spinal fluid clear, but contained many red cells when examined microscopically; pressure not above 170 mm. water, despite struggling during the reading.

I submit, therefore, that increased intracranial pressure from œdema and hæmorrhage cannot be the essential cause of traumatic stupor.

An alternative hypothesis which has been ably supported by Bagley, both from clinical observation and animal experiment, is that subarachnoid hæmorrhage may play an important part in the causation of symptoms. I have found, however, that there is no constant relation between the amount of blood in the cerebro-spinal fluid and the severity of the clinical symptoms. The cases which I have already quoted illustrate this point.

We must therefore, I believe, look for some other explanation. Direct pathological evidence is scanty but suggestive. Careful microscopical examination in cases proving fatal within the first few days, without compound fracture of the skull or compression from meningeal hæmorrhage, shows, in addition to scattered hæmorrhages, widespread alterations in the structure of nerve-cells and fibres. Similar examination, when it has occasionally been possible at a later date in cases that have survived the injury and died of intercurrent disease, has shown chromatolysis and lipoid degeneration of nerve-cells, fragmentation and fatty degeneration of myelin, and a widespread and diffuse reactive process of the micro- and macro-glia (Rosenhagen). These changes, which Rosenhagen well describes, are to be found in the form of multiple small foci throughout the cerebral cortex in its whole extent.

I am led, therefore, to the conclusion that the essential cause of traumatic stupor is direct injury to the neural tissues with subsequent reactive changes, and that increased intracranial pressure and subarachnoid hæmorrhage play a subordinate rôle.

TREATMENT.

This conclusion, if valid, will have an important bearing upon treatment. In every case of traumatic stupor lumbar puncture should be performed, and the manometer should be employed. If the spinal fluid pressure is found to be high, it should be reduced by drainage to a normal level, and further treatment, such as concentrated magnesium sulphate solution per rectum or hypertonic glucose solution intravenously, should be given to reduce intracranial pressure. Lumbar puncture in such a case should be repeated if necessary, so that the result of treatment may be followed. A heavily blood-stained fluid provides an additional indication for drainage.

Such methods of treatment, however, are to be regarded as accessory and to be employed only in the light of the information given by diagnostic lumbar puncture. The guiding principle in routine treatment will be to provide optimum conditions for the natural recovery of damaged cerebral tissues—that is, absolute rest from stimulation (aided by sedatives) in the early stages, and a carefully graduated and prolonged convalescence.

PROGNOSIS.

The ultimate prognosis in these cases is a matter of extreme difficulty. The gross disturbance of cerebral function seen in the early stages must be due to recoverable damage. But there is abundant clinical and some pathological evidence to show that there is nearly always some residual injury of a permanent kind. My own observations have taught me that among manual workers, if clouding of consciousness has persisted for longer than 24 hours after the injury, the chances of an ultimate return to full work are not greater than one in three.

Post-traumatic Cerebral Syndrome.

I would direct attention next to that group of symptoms which may be observed either in the convalescent stage after a severe injury with traumatic stupor or after a minor injury with or without concussion, and which, following Foerster, we may call the post-traumatic general cerebral syndrome. Here again we are confronted with a clinical picture in which the signs of focal cerebral damage are as a rule lacking.

The organic basis of this condition, long emphasised by Duret, has more recently been shown to comprise minor degrees of damage to the nerve-cells and fibres of the same kind as that already described in traumatic stupor (Rosenhagen), and changes in the pressure and circulation of the cerebro-spinal fluid (Bielschowsky). I have not time to refer to this important work in detail, but propose to select one or two clinical problems from this field for consideration.

The first is the extreme frequency of the symptom of vertigo. This symptom, particularly experienced view that desquamation is a direct result of the skin injury sustained at the time rash is florid. While it may be admitted in a majority of cases to be a *petitio principii* to diagnose scarlet fever from desquamation alone, many experienced observers claim to have seen desquamation following disease without any rash having been noted, and these cases have often been found to propagate fresh cases of typical scarlet fever. The difficulty is well expressed by Graves[25] in his Clinical Lectures.

"We are taught," he says, "to look upon desquamation as a result of cutaneous affections of an inflammatory character; and it is an opinion, very generally maintained, that in scarlatina, as in psoriasis, the peeling off of the cuticle depends on the peculiar state of the skin produced by inflammation." In the same lecture he quotes the case of a young lady with sore-throat and fever who desquamated and in whom, though he had her under constant observation, he nevertheless failed to observe a scarlet rash at any time during the disease. He adds that three members of the household subsequently contracted typical scarlet fever and that the lady's father developed sore-throat.

Now that a rash-producing toxin has been isolated from the causal agent of scarlet fever, the problem raised by Graves becomes none the less difficult. It is hard to imagine that desquamation really follows cases without a rash and it is always possible that in some cases the rash may be evanescent, perhaps nocturnal, and thus be missed. The Dick test may provide a method which may throw some light on the matter and it would be interesting to know whether such desquamating cases of "scarlet fever" without apparent eruption are usually positive or negative to the test and, if positive, whether the reaction becomes negative during the course of the disease.

WORCESTER INFIRMARY.—The "record" number of 2141 in-patients was received last year; their average stay was 19·5 days, and their average cost 6s. 7½d. per day. At £120 18s. 7d. the cost per occupied bed showed a reduction of £7. Out-patients, of whom there were 6369, cost 10s. 3¾d. each. The hospital is being extended at a cost of £60,000, little more than half of which has yet been obtained.

THE EFFECTS OF INJURY UPON THE BRAIN.[*]

BY C. P. SYMONDS, M.D. OXF., F.R.C.P. LOND.,
PHYSICIAN FOR NERVOUS DISEASES, GUY'S HOSPITAL;
ASSISTANT PHYSICIAN, NATIONAL HOSPITAL,
QUEEN-SQUARE.

THE effects of direct injury to the brain, as considered by the neurologist, fall naturally into two groups. The one comprises those cases which end fatally, usually within the first two or three days, with evidence post mortem of gross laceration and contusion. Cases within this group provide little opportunity for clinical study. From the moment of injury to that of death the clinical state is that of profound stupor. The second group, comprising all those patients who survive the injury, offers a field of neurological inquiry which is as fascinating as it is difficult. It is from this clinical field that I shall select certain problems for discussion.

Traumatic Stupor.

The first is that afforded by the condition which I shall designate "traumatic stupor." I have chosen this term deliberately, even though it adds to the plethora of labels. It seems to me that we need some such title, clinical and descriptive, and therefore of lasting value, to cover the major effects of cerebral injury.

That a patient is suffering from traumatic stupor is a simple statement of fact, as a rule easily determined. Whether he is suffering from cerebral contusion or cerebral œdema or the after-effects of "concussion" is a question at present unsolved. Traumatic stupor, therefore, I take, in its several degrees, to cover all those conditions in which, after recovery from the initial and complete loss, consciousness remains clouded. In its severe degree the clinical picture is one with which we are familiar in hospital experience. I shall not attempt to describe it in detail, but would draw attention to three of its most striking features:—

1. The mental state varies from that of profound stupor to a moderate clouding of consciousness, with phases of irritability, excitement, and delirium.
2. In the great majority of cases signs of focal damage to the brain are conspicuously absent.
3. In relation to the severity of the mental disturbance in the earlier stages recovery of cerebral function is remarkably rapid and complete.[†]

PATHOLOGY.

For the proper treatment of this condition we need a true estimate of its pathological basis. But direct evidence of this is, for the most part, lacking. We have therefore to depend largely upon a comparison of the clinical picture with analogous states of other causation, together with such information as may be derived from our knowledge of intracranial physiology and the disturbances of function likely to result therein from trauma.

In order to explain the association of a profound disturbance of the mental state with absence of localising signs and a relatively rapid and complete recovery, we look for a widespread or diffuse pathology. An explanation which at first sight appears acceptable is that of a general embarrassment of the capillary circulation from increased intracranial pressure, the result of multiple hæmorrhages and œdema. This ght weeks after the accident the pressure was 230 mm.; nstituents normal. Following this he had a severe bout headache, with drowsiness and vomiting, for which he as admitted to hospital, when a definite swelling of both tic discs was noted. The symptoms disappeared after day or two, and he returned to a state in which he peared normal in every way. Further examination 13 eeks after the injury showed a pressure of 300 mm., otwithstanding the absence of all symptoms. Papillœdema as still visible. Subsequently the boy attended school nd has remained well during the succeeding five years.

---

[*] Based upon a paper read at the International Neurological Congress, Berne, 1931.

[†] As judged by our somewhat coarse tests.

Thus it appears after a head injury, in the absence f any fracture of the skull or demonstrable focal sion, a state of increased intracranial pressure may ersist for at least three months. Equally striking n this case is the comparative absence of ymptoms.

If the lines of clinical distinction between these arieties of headache be valid they will serve as guides o differential treatment. The "psychogenic" type f headache will be amenable only to general measures f cerebral rest, including the removal, when present, f litigation worries. The intermittent, localised ariety of headache, related to change of posture, nay, in the light of Penfield's and Bielschowsky's work, prove capable of relief by air injection or in severe cases by operation. The rarer hydrocephalic form invites treatment by repeated lumbar puncture.

Delayed Symptoms.

There is one other aspect of the clinical problem which compels attention. In not a few cases the symptoms—sometimes severe—of cerebral injury may supervene after a considerable latent interval. The subsequent clinical course suffices to exclude late meningeal hæmorrhage (subdural hæmatoma) as the cause. For example:—

A male, aged 29, on May 7th, 1930, was struck on the head by the blunt end of an axe weighing 7 lb. He did not lose consciousness. The lacerated scalp was sewn up at hospital. After resting for 36 hours he returned to work as a labourer for five days without symptoms. On the eighth day after the accident he complained of severe headache, continuous, dull, bursting, frontal, aggravated by swinging a hammer or lying down; better when standing up; also of an intermittent stinging pain in the right sub-occipital region, unrelated to circumstance, occurring every two or three hours and associated with intense giddiness of a dizzy, drunken nature.

When seen on the tenth day after the accident he showed the following signs: right pupil larger than left; nystagmus, more to right than left; generalised hypotonia; tendon-jerks in upper limbs absent; in lower limbs sluggish; superficial reflexes normal.

He was admitted to hospital and treated with rest and hypertonic salines. On the fifteenth day he showed nystagmus, coarse and slow to the right, rapid and finer to the left. All deep reflexes were absent, even with reinforcement. The abdominal reflexes were feebly present on the right, absent on the left; both plantar responses were absent. The cerebro-spinal fluid was clear, pressure 180 mm. of water, and contained no trace of blood; protein, 0·05 per cent. This patient made a slow recovery with rest and graduated convalescence, and returned to light work four and a half months after the accident.

The occurrence of such cases is undisputed. What is the pathology of the latent interval? Marchand has suggested that it is a gradually developing reaction of the cerebral tissues to areas of necrosis produced by the initial injury—a process which he has named traumatic encephalitis. A similar view has been put forward by Osnato and Giliberti. The experimental observations of Rio-del-Hortega and Penfield go some way towards supporting this hypothesis. Nevertheless the intensity of the symptoms in such a case as I have related, and the acuteness of their onset, suggest that other factors also—probably hydrostatic—are active.

It is evident that, despite the important work which has already been done, the study of brain injuries offers a rich field of inquiry both to the clinical neurologist and to the neuropathologist.

VACCINIA AND THE PASCHEN BODY:

INFECTION EXPERIMENTS WITH CENTRIFUGALISED VIRUS FILTRATES.

BY G. HARDY EAGLES, M.D. TORONTO,
MEMBER OF BACTERIOLOGICAL STAFF, LISTER INSTITUTE, LONDON;
AND
J. C. G. LEDINGHAM, C.M.G., M.B. ABERD.,
D.SC., F.R.S.,
CHIEF BACTERIOLOGIST AND DIRECTOR OF THE INSTITUTE.

IMPROVEMENTS in technical methods of virus research have led to renewed study in recent years of the claim put forward by Paschen so long ago as 1906 that the elementary bodies discovered by him in material from vaccinial lesions might prove to be the actual ætiological agents. The present position may be thus summarised:—

(1) The elementary bodies which are readily demonstrated by appropriate staining methods are invariably found in enormous numbers not only in the characteristic skin exanthem, but also in those gross organ lesions which may follow the inoculation of highly potent virus in experimental animals.

(2) Bechhold and Schlesinger (1931) in an attempt to estimate the size of the infective virus particle in vaccinia by physical calculations based on high speed centrifugalisation experiments with virus suspensions, obtained a figure (0·21μ–0·23μ) for the diameter of the virus particle which agrees closely with the many recorded measurements of the stained Paschen body—viz., 0·2μ–0·25μ. The actual diameter of the naked Paschen body is doubtless less than 0·2μ and one of us (L.) has observed that the stained bodies contained in pure suspension in formalised saline are distinctly smaller than in their native element where their natural size is enhanced by deposition of stain and by the presence of serum proteins in the menstruum. Moreover, from the recently published experiments of Elford and Andrewes (1932) on the filtration of vaccinia virus through collodion membranes of varying porosity, the calculation is made that the size of the infective virus particle is of the order of 0·125μ–0·175μ and thus considerably less than that derived from Bechhold's centrifuge experiment.

Even direct measurements of naked bacteria and cocci are notoriously subject to error and such error must be still greater with such small objects as Paschen bodies. It would seem hardly likely, however, in view of the estimated range of diameter based on filtration and centrifuge experiments, that any claimant other than the well-known Paschen on stooping or on quick turning of the head, is as a rule unassociated with any deafness or tinnitus. Are we then dealing with a labyrinthine lesion or with damage to the structures of the brain-stem? If the latter, what is the explanation of the frequency of this system? It may possibly be found in the hypothesis of Duret.

INDIRECT INJURY TO BRAIN-STEM.

As the result of experimental work in animals and pathological observation in man, he concluded that in all cases of blunt head injury an important rôle was played by the cerebro-spinal fluid in the transmission of the force of the blow to the intracranial tissues as a whole. He observed that the structures in relation to the walls of the ventricles, and especially the aqueduct of Sylvius and fourth ventricle, suffered severely, and supposed this to be due to momentary distension of these cavities by displacement of cerebro-spinal fluid. If then we regard the vertigo as evidence of injury to the brain-stem, we may find in Duret's hypothesis an explanation of the frequency of this symptom after major or minor head injury. There is another symptom of not infrequent occurrence which may have a similar explanation: diplopia of a nuclear type. I have notes of ten cases of minor head injury (without fracture) in which diplopia was complained of during the first two or three days. Unfortunately, a detailed ophthalmological observation at the time was only possible in three. In two of these the ophthalmologist reported paresis of one superior rectus, and in the other there appeared to be paresis of one inferior rectus. In two of the others the complaint has been of diplopia on looking upwards only.

Occasionally the clinical picture of brain-stem disturbance may be much more definite. For example:—

A male, aged 19, was struck on the left parietal region on May 1st, 1930, by a cricket-ball coming from above and behind. There was no scalp wound. He was knocked down, dazed, but not unconscious. He attempted to rise but could not do so, and lay on the ground for seven or eight minutes. He then got up, changed from flannels into ordinary clothes, and went home by tram, a journey of 40 minutes. During this time he felt sick, but had no other symptoms. Arriving home he went to bed and then vomited. Subsequently he continued to vomit after every meal. He also experienced headache of two kinds: the first a continuous pressure at the back of the head, faint and intermittent; the second, attacks of pain which he referred to the forehead and described as being a pressure like that of a 20 lb. weight inside and acting downwards, lasting five minutes at a time. This latter was brought on by stooping or walking about. Shifting from the horizontal to the sitting position quickly brought it on, but change in the reverse direction gave relief.

On May 3rd, 1930, as his symptoms continued, he got up to come to hospital. He then felt as if his head were going round, and found his gait reeling and unsteady. On examination he showed a slight nystagmus, more to the right than to the left. His gait, with eyes open, appeared normal. Standing with eyes shut, his head tended to fall with the occiput to the right shoulder, and he swayed to the right and back. All deep reflexes were present and equal; the abdominals were diminished on the left, the plantar responses flexor. He was admitted to hospital and put to bed.

On May 8th, 1930, nystagmus, especially to the right, was marked; abdominal reflexes were absent. He had had no vomiting or headaches since admission to hospital. On May 12th, 1930, he had been allowed to sit up in a chair on the previous day. After an hour or so violent headache and dizziness supervened. On examination, in addition to the nystagmus, he showed absence of all tendon-jerks in the upper limbs; knee- and ankle-jerks were obtained with difficulty; abdominals were present on the right, absent on the left; the right plantar response was absent, left flexor. Lumbar puncture showed a clear fluid; pressure 240 mm. of water; no cells; protein, 0·07 per cent.

On May 22nd, 1930, nystagmus was coarse and slow to the right; fine and rapid to the left; tendon-jerks in upper limbs present and equal; right upper and lower abdominals absent; left upper and lower abdominals showed an occasional twitch; knee-jerks present, but sluggish; plantar responses flexor; no headache or vomiting. He subsequently developed measles, and was transferred to another hospital; there he had pneumonia, and therefore was not out of bed until July 9th. He declared himself free from symptoms at the time of examination (July 16th, 1930). He showed slight nystagmus to the right only, and no abnormality of posture or gait. All tendon-jerks were present and equal; abdominal reflexes present and equal, and plantar responses flexor. One year later he reported himself as back at full work (manual) and well, except for occasional headaches.

Types of Headache.

Among the several varieties of headaches encountered in this general post-traumatic state I shall attempt to distinguish three groups.

The first is that complained of by the patient in terms of discomfort rather than pain—a continuous sense of numbness or pressure, aggravated by all kinds of mental stimulus, whether internal—e.g., worry over incapacity—or external (noise, bright light). This is the kind of headache met with in psychogenic states, but also in certain psychoses—for instance, the toxic group and the depressive—and may be considered as one of the reflections in consciousness of general cerebral incapacity.

A second variety, often associated with the first, is equally frequent and of a quite different character. It is complained of as throbbing, piercing, or aching, is localised rather than diffuse, occurs in bouts, usually of brief duration, and is aggravated by change of posture and physical effort as well as by mental stimuli. This kind of headache is often referred to the situation of the initial injury and is sometimes associated with superficial tenderness. Its character and relation to postural change and effort indicate dependence upon some local physical cause, and the recent observations of Penfield, Bielschowsky, and others suggest that this may be found in the shape of loculation in the subarachnoid mesh or ventricular system.

A third and relatively uncommon variety of post-traumatic headache is that which appears in bouts of considerable duration and severity, and has the bursting quality and association with vomiting which suggests a hydrocephalic state. A bout of this kind may be provoked by alcoholic excess or by a severe physical effort—e.g., cranking a refractory automobile. The liability may remain for a short time only after the injury or may persist indefinitely. Assuming the basis of this kind of headache to be a hydrocephalus, is this obstructive—a secondary effect of brain-stem contusion—or is it communicating—due to an increased secretion or defective absorption of cerebro-spinal fluid? Certain observers have postulated a traumatic hydrocephalus of the communicating variety. The following case, recorded by my clinical assistant at Guy's Hospital at the time (Dr. N. L. Lloyd) is the most suggestive I have met with in this connexion.

A male, aged 4, was admitted to hospital unconscious after a severe head injury. He showed bruising behind and below the left mastoid and over the left frontal region. There was no clinical or X ray evidence of fractured skull. There was no striking abnormality of the cranial nerves. The muscles were flaccid with absent deep reflexes and bilateral extensor plantar responses. The cerebro-spinal fluid was intimately mixed with blood and showed a pressure of 300 mm. of water. He remained unconscious for two days and drowsy for a further four days. Subsequently he made a rapid recovery, and was discharged from hospital apparently well a month after his accident.

Five weeks after the accident the cerebro-spinal fluid pressure was 225 mm. of water; no excess of cells or protein.

Eight weeks after the accident the pressure was 230 mm.; constituents normal. Following this he had a severe bout of headache, with drowsiness and vomiting, for which he was admitted to hospital, when a definite swelling of both optic discs was noted. The symptoms disappeared after a day or two, and he returned to a state in which he appeared normal in every way. Further examination 13 weeks after the injury showed a pressure of 300 mm., notwithstanding the absence of all symptoms. Papillœdema was still visible. Subsequently the boy attended school and has remained well during the succeeding five years.

Thus it appears after a head injury, in the absence of any fracture of the skull or demonstrable focal lesion, a state of increased intracranial pressure may persist for at least three months. Equally striking in this case is the comparative absence of symptoms.

If the lines of clinical distinction between these varieties of headache be valid they will serve as guides to differential treatment. The "psychogenic" type of headache will be amenable only to general measures of cerebral rest, including the removal, when present, of litigation worries. The intermittent, localised variety of headache, related to change of posture, may, in the light of Penfield's and Bielschowsky's work, prove capable of relief by air injection or in severe cases by operation. The rarer hydrocephalic form invites treatment by repeated lumbar puncture.

Delayed Symptoms.

There is one other aspect of the clinical problem which compels attention. In not a few cases the symptoms—sometimes severe—of cerebral injury may supervene after a considerable latent interval. The subsequent clinical course suffices to exclude late meningeal hæmorrhage (subdural hæmatoma) as the cause. For example:—

A male, aged 29, on May 7th, 1930, was struck on the head by the blunt end of an axe weighing 7 lb. He did *not lose* consciousness. The lacerated scalp was sewn up at hospital. After resting for 36 hours he returned to work as a labourer for five days without symptoms. On the eighth day after the accident he complained of severe headache, continuous, dull, bursting, frontal, aggravated by swinging a hammer or lying down; better when standing up; also of an intermittent stinging pain in the right sub-occipital region, unrelated to circumstance, occurring every two or three hours and associated with intense giddiness of a dizzy, drunken nature.

When seen on the tenth day after the accident he showed the following signs: right pupil larger than left; nystagmus, more to right than left; generalised hypotonia; tendon-jerks in upper limbs absent; in lower limbs sluggish; superficial reflexes normal.

He was admitted to hospital and treated with rest and hypertonic salines. On the fifteenth day he showed nystagmus, coarse and slow to the right, rapid and finer to the left. All deep reflexes were absent, even with reinforcement. The abdominal reflexes were feebly present on the right, absent on the left; both plantar responses were absent. The cerebro-spinal fluid was clear, pressure 180 mm. of water, and contained no trace of blood; protein, 0·05 per cent. This patient made a slow recovery with rest and graduated convalescence, and returned to light work four and a half months after the accident.

The occurrence of such cases is undisputed. What is the pathology of the latent interval? Marchand has suggested that it is a gradually developing reaction of the cerebral tissues to areas of necrosis produced by the initial injury—a process which he has named traumatic encephalitis. A similar view has been put forward by Osnato and Giliberti. The experimental observations of Rio-del-Hortega and Penfield go some way towards supporting this hypothesis. Nevertheless the intensity of the symptoms in such a case as I have related, and the acuteness of their onset, suggest that other factors also—probably hydrostatic—are active.

It is evident that, despite the important work which has already been done, the study of brain injuries offers a rich field of inquiry both to the clinical neurologist and to the neuropathologist.

VACCINIA AND THE PASCHEN BODY:

INFECTION EXPERIMENTS WITH CENTRIFUGALISED VIRUS FILTRATES.

BY G. HARDY EAGLES, M.D. TORONTO,
MEMBER OF BACTERIOLOGICAL STAFF, LISTER INSTITUTE, LONDON;
AND
J. C. G. LEDINGHAM, C.M.G., M.B. ABERD.,
D.SC., F.R.S.,
CHIEF BACTERIOLOGIST AND DIRECTOR OF THE INSTITUTE.

IMPROVEMENTS in technical methods of virus research have led to renewed study in recent years of the claim put forward by Paschen so long ago as 1906 that the elementary bodies discovered by him in material from vaccinial lesions might prove to be the actual ætiological agents. The present position may be thus summarised:—

(1) The elementary bodies which are readily demonstrated by appropriate staining methods are invariably found in enormous numbers not only in the characteristic skin exanthem, but also in those gross organ lesions which may follow the inoculation of highly potent virus in experimental animals.

(2) Bechhold and Schlesinger (1931) in an attempt to estimate the size of the infective virus particle in vaccinia by physical calculations based on high speed centrifugalisation experiments with virus suspensions, obtained a figure (0·21μ–0·23μ) for the diameter of the virus particle which agrees closely with the many recorded measurements of the stained Paschen body—viz., 0·2μ–0·25μ. The actual diameter of the naked Paschen body is doubtless less than 0·2μ and one of us (L.) has observed that the stained bodies contained in pure suspension in formalised saline are distinctly smaller than in their native element where their natural size is enhanced by deposition of stain and by the presence of serum proteins in the menstruum. Moreover, from the recently published experiments of Elford and Andrewes (1932) on the filtration of vaccinia virus through collodion membranes of varying porosity, the calculation is made that the size of the infective virus particle is of the order of 0·125μ–0·175μ and thus considerably less than that derived from Bechhold's centrifuge experiment.

Even direct measurements of naked bacteria and cocci are notoriously subject to error and such error must be still greater with such small objects as Paschen bodies. It would seem hardly likely, however, in view of the estimated range of diameter based on filtration and centrifuge experiments, that any claimant other than the well-known Paschen body is likely to be forthcoming for the position of infective virus particle.

(3) One of us (Ledingham, 1931, 1932) has reported that pure suspensions of elementary bodies in vaccinia and fowl-pox can be obtained in an indifferent medium of formolised saline and that such suspensions are specifically agglutinated by the serum of vaccinated animals. Their agglutination can be readily followed in hanging drop preparations with a two-thirds inch objective and the stained clumps are found to consist wholly of elementary bodies. Moreover, after a single dose of virus, agglutinins appear in the serum, rise to a maximum, and slowly fall precisely as do agglutinins in response to any bacterial antigen.

(4) The elementary bodies have recently been shown by Nauck and Paschen (1932) to increase in numbers in cultures of vaccinia virus grown in vitro in the presence of testicular tissue, and we may state here that we have been able to demonstrate the presence of numerous Paschen bodies in stained preparations of vaccinia cultures grown by Eagles and McClean (1931) in a cell-free medium.

OBJECT OF PRESENT EXPERIMENTS.

The experiments here recorded were undertaken to secure further evidence in support of the claim for the Paschen body to be the actual infective agent. They are substantially amplifications of such experiments as those of Ward (1929) and Tang (1930) who followed up their successful filtrations of vaccinia virus through low-grade candle filters by centrifuging the filtrates and demonstrating a concentration of virus in the bottom layers. The results certainly supported their view that the infective particle may be " of considerable size " and that the nature of the material submitted to centrifugalisation rather precluded the possibility of virus being simply adsorbed on inert particles which had escaped the filter. Centrifugalisation of carefully prepared suspensions of neuro-vaccine by Bland (1929) also supported strongly the view that the virus of vaccinia can be thrown down by the centrifuge given sufficient time and speed.

EXPERIMENTAL METHODS.

Our experiments have all been carried out with Berkefeld " V " filtrates of vaccinia virus which have been submitted to centrifugalisation with a new model high speed centrifuge (manufactured by Baskerville and Lindsay, Manchester) capable of speeds up to 14,000 revolutions per minute with a 10 c.cm. load. One of us (E.) was responsible for the centrifugalisation and the experimental testing of the various supernatants and deposits, while the other undertook the examination of the stained deposits for the presence of Paschen bodies.

For the cutaneous inunction of rabbits two strains of virus were used—viz., a testicular strain of rabbit origin and a purely dermal strain of sheep origin. Some few experiments were also carried out with testicular tissue infected with neuro-vaccine, but these on the whole were less satisfactory, so far as completeness of deposition of virus was concerned, possibly because the filtrates were heavily charged with hæmoglobin and perhaps also because the Paschen body content of the filtrates was very high. The filtration technique was that employed in former experiments by Green and Eagles (1931).

The lapine was removed from the backs of rabbits on the third or fourth day after inunction. The pulp was thoroughly ground in a mortar, no sand or other material being used to facilitate grinding. After suitable dilution with distilled water the virus suspension was lightly centrifugalised, then passed through coarse filter paper, and finally through a Berkefeld " V " candle. All filtra used were water-clear, bacteriologically sterile, and of f potency when tested by intradermal inoculation in t rabbit.

EXPERIMENTAL DATA.

The three experiments (A, B, and C) record in detail below are selected from a set of about in all, because they illustrate best the effect of var tion in speed and time of action of centrifuge on t deposition of virus from filtrates and on the furtl purification of macroscopically visible or invisil deposits by repeated saline washings.

Experiment A (Table I.).—To determine how t concentration of virus contained in filtrate w affected by centrifugalisation of 4 c.cm. filtrate f 30 min. at 10,000 rev. per min.

After removal from the centrifuge the supernatant flu was carefully pipetted off in 1 c.cm. amounts. The botto c.cm. was found to be in contact with a faintly visil deposit which was incorporated with it by thorough mixi after being scraped from the glass with a platinum spatu Samples from the upper c.cm., the third c.cm., and the four c.cm. containing the scraped off deposit were titrated f potency on the rabbit by intradermal inoculation in paral with the unspun filtrate as control. Table I. shows th the fourth c.cm. and the third c.cm. contained by far t major portion of the virus, the end-point being not nea reached in the case of the former. The figures in the Tal represent the diameters (or average diameters) of ca reaction at its height, but it should be borne in mind th for comparative purposes the cubes of the diameters are mo strictly appropriate.

Examination for Paschen bodies.—Film from fourth c.c showed very large numbers of elementary bodies mos in carpets but occasionally in agglomerations. In the upp and third c.cms. only very few bodies could be detect

m. = millimetre. ± = reaction appearing faintly red b not measurable.

Experiment B (Table II.).—Centrifugalisation f one hour periods at 12,000–14,000 rev. per min.

The entire supernatant was removed, care being taken avoid disturbance of deposit in contact with the glass. Th supernatant was again spun at the same speed for one hou It was removed from possibly present but invisible depos and spun a third time for one hour. In this way thr deposits were obtained for titration purposes along wi samples of the various supernatants and the unspun filtrat Only the first deposit was visible to the naked eye. Th three deposits were carefully scraped and mixed each wi three drops of saline from a standard drop pipette. Table I shows that the major portion of the virus was present the first deposit after one hour's spinning, while the secor and third deposits contained diminishing amounts of viru The supernatant which had been submitted to two hour spinning contained only a trace of virus, but after thre hours' spinning was entirely devoid of activity.

Examination for Paschen bodies.—Film from first depos showed colossal numbers of elementary bodies mostl entirely in big and little aggregations and attached to or i the neighbourhood of amorphous flaky matter. The hig speed of spinning had obviously caused packing of the bodi he glass. The second deposit contained only occasional ll packets, while the third appeared entirely free of ies. In the two supernatants elementary bodies could with certainty be detected.

dep. = deposit; sup. = supernatant.

Experiment C (Table III.).—To determine the otency of repeatedly washed deposit. Centrifugalisaion for one hour at 12,000–14,000 rev. per min.

A small amount of fluid inevitably remains in contact with he deposit when the supernatant is removed. In order to ee the elementary bodies from this fluid the supernatant as entirely removed and the deposit carefully incorporated ith 4 c.cm. of salt solution. This saline suspension was ow spun for one hour and the deposit again washed in saline nd re-spun. This twice-washed deposit was incorporated n three drops of saline and along with the second saline upernatant and the primary supernatant removed from he first deposit, submitted to potency test. Table III. hows that the virus was concentrated in the twice-washed eposit, while the second saline washing was entirely free f virus. A small amount of virus was, as might be expected, present in the primary supernatant.

Examination for Paschen bodies.—Films of the final twice-washed deposit showed colossal numbers of elementary bodies mostly in small and large packets, but occasionally in large sheets. In the other fluids they were not definitely detected.

If the Paschen bodies are responsible for the potency of deposits it might be expected that the great concentration of virus in the latter, as shown by titration, would be reflected in the number of bodies found therein, and further, that deposits and supernatants which vary in potency would be associated with similar variations in their Paschen body content. The usual technique was to dip a 2 mm. platinum loop into the fluid to be tested for potency (whether supernatant, or bottom fluid with incorporated deposit, or washed deposit made up with saline). After withdrawal the fluid was spread as thinly as possible on a slide and treated and stained by the approved technique (see Med. Res. Council's System of Bacteriology, 1931, vol. ix., p. 132). Invariably the film from the first deposit has shown the presence of what would appear to be the great bulk of the Paschen bodies originally contained in the fluid spun, while in other fluids (primary supernatants and washings) only small numbers of bodies can be detected with certainty. It has been the practice of those experienced in the staining of elementary bodies never to diagnose their presence unless they occur in clearly recognisable collections large or small. Some method of enumeration is desirable, and doubtless if it were possible to disperse the collections and to obtain a homogeneous distribution the problem of enumeration would be greatly simplified.

DISCUSSION.

The representative experiments we have here recorded on the effect of high-speed centrifugalisation on virus filtrates and on the broad correlation of potency of fluids tested with their Paschen body content leave, in our opinion, no escape from the conclusion that these deposits, visible or invisible, owe their potency to the presence of Paschen bodies in them. The speed and the period of centrifugalisation are important for securing a virus-free supernatant. A speed of 10,000–11,000 rev. per min. acting for one hour has been found to result either in a concentration of the virus in the lower layer of the fluid or in a deposit which is so lightly attached to the glass that the supernatant fluid cannot be completely removed without disturbing the deposit. If a small quantity of gelatin is placed in the tip of pointed tubes before the virus filtrate is added, the elementary bodies can be held. The presence of gelatin however does not favour the search for the bodies in stained films. The experiments in which deposits were submitted to repeated washings in saline are, in our view, particularly convincing, inasmuch as the stained preparations of the potent fluids showed rich carpets of elementary bodies and an almost complete absence of other stainable matter formed or amorphous. As the saline menstruum itself was proved to contain no virus the conclusion is irresistible that the infecting agent is the Paschen body, though it is always possible to assume that the true virus may be something attached to the surfaces of Paschen bodies, but incapable of existing apart from them or of being dissociated by mechanical means such as repeated washing. In the present state of knowledge such criticism can have little cogency and, indeed, might be logically applied to any generally accepted causal bacterium on the ground that it is merely the vehicle of some lesser hypothetical agent.

With the further knowledge from the serological side (Ledingham) and the demonstration by Nauck and Paschen that in successful artificial cultures Paschen bodies are present in large numbers—a claim which we have been able to confirm for the cultures obtained by Eagles and McClean in cell-free media—the evidence in support of the Paschen body as the ætiological agent of vaccinia would seem to be reasonably complete. It is of very great interest in this connexion that Bedson (1932) has been able, by very similar means to those employed in this work, to secure evidence that the minute bodies found in psittacosis represent in all probability the actual infective agents. To conclude, it remains to be shown that artificial cultures starting from pure seedings of Paschen bodies are possible, and doubtless body is likely to be forthcoming for the position of infective virus particle.

(3) One of us (Ledingham, 1931, 1932) has reported that pure suspensions of elementary bodies in vaccinia and fowl-pox can be obtained in an indifferent medium of formolised saline and that such suspensions are specifically agglutinated by the serum of vaccinated animals. Their agglutination can be readily followed in hanging drop preparations with a two-thirds inch objective and the stained clumps are found to consist wholly of elementary bodies. Moreover, after a single dose of virus, agglutinins appear in the serum, rise to a maximum, and slowly fall precisely as do agglutinins in response to any bacterial antigen.

(4) The elementary bodies have recently been shown by Nauck and Paschen (1932) to increase in numbers in cultures of vaccinia virus grown in vitro in the presence of testicular tissue, and we may state here that we have been able to demonstrate the presence of numerous Paschen bodies in stained preparations of vaccinia cultures grown by Eagles and McClean (1931) in a cell-free medium.

OBJECT OF PRESENT EXPERIMENTS.

The experiments here recorded were undertaken to secure further evidence in support of the claim for the Paschen body to be the actual infective agent. They are substantially amplifications of such experiments as those of Ward (1929) and Tang (1930) who followed up their successful filtrations of vaccinia virus through low-grade candle filters by centrifuging the filtrates and demonstrating a concentration of virus in the bottom layers. The results certainly supported their view that the infective particle may be " of considerable size " and that the nature of the material submitted to centrifugalisation rather precluded the possibility of virus being simply adsorbed on inert particles which had escaped the filter. Centrifugalisation of carefully prepared suspensions of neuro-vaccine by Bland (1929) also supported strongly the view that the virus of vaccinia can be thrown down by the centrifuge given sufficient time and speed.

EXPERIMENTAL METHODS.

Our experiments have all been carried out with Berkefeld " V " filtrates of vaccinia virus which have been submitted to centrifugalisation with a new model high speed centrifuge (manufactured by Baskerville and Lindsay, Manchester) capable of speeds up to 14,000 revolutions per minute with a 10 c.cm. load. One of us (E.) was responsible for the centrifugalisation and the experimental testing of the various supernatants and deposits, while the other undertook the examination of the stained deposits for the presence of Paschen bodies.

For the cutaneous inunction of rabbits two strains of virus were used—viz., a testicular strain of rabbit origin and a purely dermal strain of sheep origin. Some few experiments were also carried out with testicular tissue infected with neuro-vaccine, but these on the whole were less satisfactory, so far as completeness of deposition of virus was concerned, possibly because the filtrates were heavily charged with hæmoglobin and perhaps also because the Paschen body content of the filtrates was very high. The filtration technique was that employed in former experiments by Green and Eagles (1931).

The lapine was removed from the backs of rabbits on the third or fourth day after inunction. The pulp was thoroughly ground in a mortar, no sand or other material being used to facilitate grinding. After suitable dilution with distilled water the virus suspension was lightly centrifugalised, then passed through coarse filter paper, and finally through a Berkefeld " V " candle. All filtrates used were water-clear, bacteriologically sterile, and of fair potency when tested by intradermal inoculation in the rabbit.

EXPERIMENTAL DATA.

The three experiments (A, B, and C) recorded in detail below are selected from a set of about 15 in all, because they illustrate best the effect of variation in speed and time of action of centrifuge on the deposition of virus from filtrates and on the further purification of macroscopically visible or invisible deposits by repeated saline washings.

Experiment A (Table I.).—To determine how far concentration of virus contained in filtrate was affected by centrifugalisation of 4 c.cm. filtrate for 30 min. at 10,000 rev. per min.

After removal from the centrifuge the supernatant fluid was carefully pipetted off in 1 c.cm. amounts. The bottom c.cm. was found to be in contact with a faintly visible deposit which was incorporated with it by thorough mixing after being scraped from the glass with a platinum spatula. Samples from the upper c.cm., the third c.cm., and the fourth c.cm. containing the scraped off deposit were titrated for potency on the rabbit by intradermal inoculation in parallel with the unspun filtrate as control. Table I. shows that the fourth c.cm. and the third c.cm. contained by far the major portion of the virus, the end-point being not nearly reached in the case of the former. The figures in the Table represent the diameters (or average diameters) of each reaction at its height, but it should be borne in mind that for comparative purposes the cubes of the diameters are more strictly appropriate.

Examination for Paschen bodies.—Film from fourth c.cm. showed very large numbers of elementary bodies mostly in carpets but occasionally in agglomerations. In the upper and third c.cms. only very few bodies could be detected.

m. = millimetre. ± = reaction appearing faintly red but not measurable.

Experiment B (Table II.).—Centrifugalisation for one hour periods at 12,000–14,000 rev. per min.

The entire supernatant was removed, care being taken to avoid disturbance of deposit in contact with the glass. This supernatant was again spun at the same speed for one hour. It was removed from possibly present but invisible deposit and spun a third time for one hour. In this way three deposits were obtained for titration purposes along with samples of the various supernatants and the unspun filtrate. Only the first deposit was visible to the naked eye. The three deposits were carefully scraped and mixed each with three drops of saline from a standard drop pipette. Table II. shows that the major portion of the virus was present in the first deposit after one hour's spinning, while the second and third deposits contained diminishing amounts of virus. The supernatant which had been submitted to two hours' spinning contained only a trace of virus, but after three hours' spinning was entirely devoid of activity.

Examination for Paschen bodies.—Film from first deposit showed colossal numbers of elementary bodies mostly entirely in big and little aggregations and attached to or in the neighbourhood of amorphous flaky matter. The high speed of spinning had obviously caused packing of the bodies thout symptoms. After treatment ceased, thick ›od films were taken daily from all patients who ıld be induced to remain in hospital under observa-›n. In one case benign tertian parasites reappeared the blood nine days after completion of a seven-day urse of quinine treatment (grs. 30 daily). Accord-gly, in Table III., only those cases who remained ıder subsequent observation for nine days or more .ve been included.

Thirteen relapses were noted among 34 quinine-reated cases.† Among a total of 19 cases treated rith atebrin and observed, on an average, over omewhat longer periods, no relapses occurred; and, ılthough the numbers observed were comparatively ›mall, the results appear to indicate that atebrin nay be superior to quinine in preventing relapses.

ACTION OF QUININE AND OF ATEBRIN ON GAMETOCYTES.

Disappearance of the gametocytes during treatment.—In the benign tertian cases, treatment with atebrin brought about a rapid disappearance of gametocytes, and, in this respect, it was similar to quinine. The effect of both quinine and atebrin on quartan gametocytes was less marked than on those of *P. vivax*, but in no case were the gametocytes of *P. malariæ* found in the blood later than the twelfth day after the inception of treatment, although administration of the drugs had ceased on the seventh day. The resistance of the gametocytes of *P. falciparum* to quinine is well known, and they may persist for some weeks after the trophozoites have disappeared, even though the quinine treatment is continued. In the two series of cases under discussion, neither quinine nor atebrin appeared to have any directly destructive effect on the gametocytes in the blood of the subtertian patients.

Interference with the viability of gametocytes.—Plasmoquine has been shown to affect the viability of subtertian gametocytes in such a way as to prevent them developing further in the mosquito. With this in mind, experiments were undertaken to find whether atebrin affected the viability of gametocytes in the same way. Again, cases treated with quinine were used as controls, and batches of anopheline mosquitoes were fed at certain times during the period of treatment on (*a*) cases treated with quinine, and (*b*) cases treated with atebrin. Neither drug was found to affect the viability of subtertian or benign tertian gametocytes, and the results are given in Table IV.

TOXIC SYMPTOMS.

Of the 50 patients treated with atebrin, two complained of headache and four of abdominal pain. Headache in the supra-orbital region occurred on the sixth day of treatment in one case, and two days after a seven-day course of treatment had been completed in the other.

Abdominal pain was severe in three cases and mild in the remaining one. It was intermittent in character and lasted for some hours. The pain was unaccompanied by vomiting, and occurred in the epigastric region as early as the fourth day of treatment, and as late as the fifth day after treatment had been stopped. It was difficult to be sure, in all cases, that the headache and abdominal pains were due to atebrin, but there was reasonable certainty that the severe epigastric symptoms were caused by the drug.

In seven cases a yellow discoloration of the skin, whites of the eys, or both, was noted. This seemed to be due to a dyeing effect of the drug on the tissues and not to jaundice, for serum from such cases, when tested, did not show excess of serum bilirubin. The depth of colour of the skin varied from a faint yellow, occurring in six cases, to a more marked yellow in one case. This discoloration of the skin or scleræ made its appearance on the sixth to the ninth day (average eighth day—i.e., the day after treatment ceased), and remained for periods varying from 8 to 15 days, when the tissues regained their normal colour. All seven cases had received comparatively knowledge of the manner of growth and division of the elementary body will then be forthcoming.

---

† Among the cases treated with quinine, the form of parasite occurring on relapse seems to deserve comment, for in all cases except two benign tertian parasites were found. Previously, Fletcher[2] in Malaya noted the frequency with which benign tertian parasites were present in the blood during a relapse, although when the patients first came for treatment other forms of parasite were found. Similar observations have been made in other countries; and the possibility that one species of malarial parasite becomes converted into another has been seriously considered as an explanation of these findings. As a more likely explanation, some authorities put forward the hypothesis that, in certain mixed infections, one species becomes predominant during the acute phase of the malarial attack and remains predominant for some time. If this may be accepted, the results given in the table above suggest that an unexpectedly large proportion of malarial infections in Malaya are mixed; but, during the acute phase, when the patient seeks treatment, one or other of the parasite species predominates and is the only one found; the other, or latent form of parasite, is probably sporulating quietly in a backwater of the blood stream, or occurs in such small numbers as not to be evident in thin or thick blood films. These latent forms may possess a greater resistance to the action of drugs or, by reason of their position in the body, may fail to be subjected to the drug in its usual concentration; either possibility would explain their tendency to appear on relapse.

SUMMARY.

(1) By high-speed centrifugalisation it has been possible to deplete Berkefeld filtrates of vaccinia virus almost entirely of their virus content and to recover the great bulk of the virus in deposits consisting in the main of Paschen bodies.

(2) Such deposits after repeated washings in saline retain their potency, while the saline menstruum in which the bodies are suspended has been entirely depleted of virus.

(3) In the light of these experiments the present status of the Paschen body is discussed, and the conclusion is reached from all the evidence now available that the cause of vaccinia is the Paschen body.

A REPORT ON FIFTY CASES OF MALARIA TREATED WITH ATEBRIN.

A NEW SYNTHETIC DRUG.

BY RICHARD GREEN, M.D. MELB., D.T.M. LIVERP.,
MALARIA RESEARCH OFFICER I., FEDERATED MALAY STATES; MEMBER OF THE MALARIA COMMISSION OF THE LEAGUE OF NATIONS.

(From the Institute for Medical Research, Kuala Lumpur.)

ATEBRIN, originally called erion, has been produced recently by the makers of plasmoquine. Its composition has not been divulged, and the properties of the drug are being investigated in Europe, Asia, and America. According to Schulemann,[1] atebrin is related chemically to plasmoquine, and both drugs have been evolved by using the structural formula of methylene-blue as a starting-point.

Dr. O. Urchs, of Calcutta, has kindly supplied details of preliminary tests made with atebrin in Europe, and has requested the Institute of Medical Research, Kuala Lumpur, to undertake an investigation concerning the efficacy of this new drug in the treatment of malaria. Atebrin was received in the form of tablets, each of which was said to contain 0·1 g. of the drug. The dosage recommended was about one-sixth that of quinine. The drug is somewhat bitter to taste and is readily soluble in water, producing in it a bright yellow colour. Unlike plasmoquine, and like quinine, atebrin shows fluorescence in high dilution under ultra-violet radiation.

An inquiry regarding the properties of this drug is still proceeding. So far, 50 cases of malaria have completed seven days' treatment with atebrin. Subsequently, the patients have been kept under daily observation as long as possible. The 50 cases mentioned comprised 16 benign tertian, 24 subtertian, and 10 quartan, and consisted of male Tamils, Chinese, and Sikhs whose ages ranged from 6 to 50 years. The majority gave a history of repeated attacks of malaria occurring over a period of six months or more; 46 similar individuals, suffering from malaria, were treated for seven days with quinine bihydrochloride, grs. 30 daily, in the form of a mixture. These control cases were used for comparison in all particulars. Fuller details, such as the degree of infection, method of treatment, &c., regarding both series of cases, are given later.

COMPARISON OF PARASITOCIDAL PROPERTIES.

Thick blood films from each case were examined daily. In both the atebrin and quinine-treated cases the asexual parasites disappeared from the blood, as a rule, within the seven-day treatment period, but quartan gametocytes tended to persist after the seventh day, later to disappear; while in the subtertian cases the gametocytes seemed unaffected by the drugs. For this reason the findings regarding quartan and subtertian gametocytes are omitted from Table I., which compares the average period of persistence of all parasites in the benign tertian cases and of the asexual parasites only in the subtertian and quartan series.

TABLE I.—*Parasitocidal Properties Compared.*

		Quinine bihydrochloride grs. 30 daily (2·0 g.) *for 7 days.*		Atebrin grs. 3 to 6 daily (0·2 to 0·4 g.) for 7 days.	
		Cases.	Days.	Cases.	Days.
Blood parasites.*	B.T.	17	3·6	16	2·4
	S.T.†	9	2·8	24	3·5
	Q.†	20	5·8	10	4·4

* Average number of days parasites persisted in the blood (thick films), including day when treatment commenced.
† Denotes trophozoites and schizonts only.

With regard to the rate of destruction of malarial parasites in the blood, atebrin appears to compare very favourably with quinine in the treatment of benign tertian and quartan malaria. The trophozoites of *P. falciparum*, however, persisted longer among the atebrin-treated cases.

COMPARISON OF THE DURATION OF THE FEBRILE PERIOD.

The temperature of each patient was taken every four hours, and the hour when treatment commenced was noted on the temperature chart. The duration of the febrile period was estimated from the time when the first dose of the drug was given, to the time when the temperature ceased to rise to 99° F. or over. In some cases,[*] despite the presence of large numbers of parasites in the blood, the temperature remained below 99° F., and these cases are omitted from Table II.

TABLE II.—*Duration of the Febrile Period.*

		Quinine bihydrochloride.		Atebrin.	
		(Same dosage as Table I.)			
		Cases.	Hours.	Cases.	Hours.
Fever* ..	B.T.	12	30	14	33
	S.T.	8	30	20	34
	Q.	12	58	10	43

* Average period of persistence of fever (temp. 99° F. or over) from commencement of treatment.

RELAPSE AFTER TREATMENT.

The term relapse is used, in this instance, to denote the reappearance of parasites in the blood, with or idity to prevent mosquitoes becoming infected m benign tertian cases within three or four days er treatment commences. Among gametocyte riers of *P. falciparum* neither atebrin nor quinine y be regarded as an efficient drug in preventing infection of mosquitoes which have access to such tients under treatment.

---

[*] Patients who are infected with malarial parasites but who remain afebrile for long periods without treatment are not infrequently encountered in Malaya. Some of them exhibit an extraordinary degree of tolerance to the presence of comparatively large numbers of malarial parasites in the blood.

5. The optimum dosage of atebrin for all forms of laria is probably 0·1 g. per 15 kg. body-weight r day, given for a period of six to seven days. eatment should be preceded by preliminary purga- n, and it is suggested that the urine should be amined for the presence of the drug each day in cases under treatment. Late appearance of the ug in the urine may be taken as an indication that e drug is accumulating in the body in greater ncentrations than desirable, and this may give se to discoloration of the skin or scleræ.

6. If the cost of treatment with atebrin compares vourably with that of quinine, this new drug sumes an added importance, particularly if it is own definitely to be more effective than quinine preventing relapses when used for short courses of eatment. Atebrin thus deserves full and wide- read investigation, but final opinion regarding its neral use in malaria and its toxicity should be ithheld pending completion of such investigations.

I am indebted to Dr. A. Neave Kingsbury, Director f the Institute for Medical Research, F.M.S., for ermission to undertake the investigation and to ublish this paper. Dr. O. Urchs, of Calcutta, has indly supplied large quantities of atebrin, together ith details of preliminary tests made in Europe. am also indebted to Dr. W. E. Diamond for the rivilege of treating with this new drug cases of alaria admitted to the District Hospital, Kuala umpur.

THE TREATMENT BY MARMITE OF MEGALOCYTIC HYPERCHROMIC ANÆMIA

OCCURRING IN IDIOPATHIC STEATORRHŒA (CŒLIAC DISEASE).

BY JANET M. VAUGHAN, D.M. OXF.,
BEIT MEMORIAL FELLOW;
AND
DONALD HUNTER, M.D., F.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE LONDON HOSPITAL.

(From the Bernhard Baron Institute of Pathology, the London Hospital.)

IN an investigation of a group of 15 cases of idiopathic steatorrhœa (cœliac disease) associated with tetany and often with bone deformities[1] two were found to have a hyperchromic megalocytic type of anæmia. In view of the observation of Wills[32] that marmite was as effective as liver extract in the treatment of tropical megalocytic anæmia, it was decided to test its effect in the present cases. The nature and significance of the response obtained by such treatment form the subject of this paper.

INTRODUCTION.

Gee[10] in his original description of cœliac disease states that "cachexia, a fault of sanguification betokened by pallor and a tendency to dropsy, is a constant symptom." Subsequent observers have shown that the blood picture may be extremely variable, depending presumably upon which of the factors essential for hæmopoiesis are lacking. There may be no abnormality.[1, 9, 16] The majority of cases show a hypochromic anæmia,[9, 13, 25, 28] but 20 cases with a hyperchromic megalocytic anæmia have been reported, and we have a small group with an erythroblastic type of anæmia now under observation.[1]

The recorded cases of megalocytic hyperchromic anæmia in which full blood counts are available are shown in the Table. In addition, Rossier[23] has described three cases in adults of pernicious anæmia associated with diarrhœa, tetany, and disturbances of blood calcium, which were possibly cases of cœliac disease, especially as free hydrochloric acid was present in two. Witts[33] calls his case one of chylous diarrhœa, but since the patient is described as having "such scoliosis that his spine seems to have shrunken," the inclusion in the present group seems justified. The case described by Hampson and Shackle[14] was thought at the time to be one of renal dwarfism, but as her blood-urea was as low as 13 mg. per 100 c.cm. and a trace of albumin in the urine occurred on one occasion only, it is more likely that she was a cœliac dwarf, and she has therefore been included. Thaysen[28] states that 11 of his cases had at one time a hyperchromic anæmia, but no mention is made of the appearance of the red blood-cells. They are not therefore tabulated.

Two cases described by Schaefer[24] and Hegler[15] as non-tropical sprue are also not included, as, though they had severe steatorrhœa and a megalocytic hyperchromic anæmia, it is not clear that they had either tetany or disturbances of calcium metabolism associated with bone deformities.

CASE REPORTS.

CASE 1.—A married woman, aged 40 years (L. H., Reg. No. 40997/1930). All her life she has had attacks of diarrhœa with yellow offensive slimy motions and intervals of relative freedom. She improved when she was 7 years old, but became worse after her only child was born, 11 years ago. The attacks last about five days, when she passes about six stools a day. Between attacks the bowels are open three times daily and she may have to get up four times at night. The diarrhœa tends to become worse in warm surroundings. She first noticed cramps in her hands and feet in June, 1930.

On Feb. 18th, 1928, she was an in-patient under the care of Dr. A. M. H. Gray at University College Hospital for a persistent pustular dermatitis affecting the limbs, face, scalp, and to a less extent the trunk. A pure culture of *Staphylococcus aureus* was obtained from the lesions. She was treated by vaccines, iron, and arsenic, and a variety of liniments and proprietary foods containing vitamins.

On Feb. 22nd, 1930, she became an in-patient under the care of the Medical Unit at University College Hospital, when a diagnosis of pancreatic insufficiency was made. The total fat in the stools at that time was 71·2 per cent., of which 45·2 per cent. was neutral fat, and 26·0 per cent. fatty acid. The test-meal showed free hydrochloric acid. The red blood-cells were 4,000,000 per c.mm.; hæmoglobin, 68 per cent.; colour-index, 0·85; white blood-cells, 4200 per c.mm.

On June 9th, 1930, she was admitted to the London Hospital complaining of diarrhœa and cramps in the hands and feet. Appetite excellent.

Clinical examination.—Weight 7 st. 2 lb. Height 5 ft. 1¾ in. A pale thin woman, with a dry skin and seborrhœa of the right eyebrow. There was no bone deformity. The Chvostek and Trousseau signs were positive. Slit-lamp examination showed fine scattered opacities throughout the large doses of the drug (0·4 g. daily), and in all the excretion of the drug was found to be delayed; that is, it first appeared in the urine from the sixth to the thirteenth day (average eighth day), whereas, in cases showing no tinting of the skin or scleræ, the urine generally showed the characteristic colour of atebrin about the third or fourth day.

Atebrin did not appear to give rise to albuminuria, and in two cases of quartan malaria an initial albuminuria disappeared during administration of the drug.

GENERAL.

Notes on patients investigated and methods used.—Further details regarding the patients under treatment are given in Table V.

* M.I. = Average degree of malarial infection on first day of treatment, expressed as numbers of trophozoites, schizonts, and gametocytes per c.mm. of blood.

The patients were isolated in a special ward and were examined twice daily during the period of treatment and observation. Treatment was preceded by routine purgation. The drugs were given twice daily and, when the patients received 0·3 g. of atebrin each day, 0·2 g. was given in the morning and 0·1 g. in the evening. Every precaution was taken to see that the drugs were actually swallowed and were not vomited subsequently. The temperature was taken every four hours, and the following observations were made daily: Spleen measurements, hæmoglobin percentages (Dare), and counts of the numbers of parasites in thick blood films, using the fowl-corpuscle method (Sinton [3]). Each patient was weighed daily, and the urine was examined each day for the presence of albumin, quinine, and atebrin.

Urine tests.—In the information accompanying the supply of atebrin it was stated that "by means of ether atebrin can be extracted from urine which has been rendered alkaline, and if the residue resulting from the evaporation of ether is dissolved in concentrated sulphuric acid this assumes a yellow colour, strongly fluorescent." It was found, however, that among patients taking atebrin the characteristic yellow colour of the drug became apparent in the urine by rendering it acid and heating it. This colour was best seen by viewing the urine in the test-tubes from above downwards. Although this was not so delicate a test as the ether extraction mentioned above, daily observations on the urine of atebrin-treated cases showed that the drug appeared in the urine about the third or fourth day after treatment commenced, but could still be detected by this rough test up to the eighth or ninth day after treatment had ceased. These observations seem to indicate that the drug tends to accumulate in the body and to be excreted slowly.

When dissolved in water the yellow colour of atebrin persisted up to dilutions of 1 in 102,000; luminescence under ultra-violet radiation was still apparent in dilutions of 1 in 818,000, while precipitation with Mayer's reagent occurred up to dilutions of 1 in 409,000. The urine of patients taking atebrin did not, however, show precipitation with Mayer's reagent, although showing the yellow colour of atebrin.

It was thought that ultra-violet light might be of use in detecting small quantities of atebrin in urine. This, however, was a failure, for it was found that all specimens of urine, from normal and untreated individuals, contained substances which glowed under ultra-violet light, and these substances interfered with the detection of drugs that were similarly luminescent.

Dosage of atebrin.—Table VI. shows the dosage used among the 50 cases mentioned.

TABLE VI.

Daily dose.	Patients treated.			Remarks.
	B.T.	S.T.	Q.	
				Dose regarded as—
0·2 g.	4	4+1 (boy)	2	Too small for adults.
0·3 g.	6	8	5	Adequate for adults.
0·4 g.	6	11	3	Too large for adults.

The inclusion in Tables I. and II. of ten adults treated with 0·2 g. atebrin daily, which is regarded as an inadequate dose, has tended to prolong the average period of persistence of parasites in the blood, also the duration of fever, as shown in these Tables.

The patients receiving atebrin treatment had an average body-weight of 105 lb. (about 48 kg.), which is below the average body-weight of Europeans. It is concluded, from the results observed among the cases treated with daily doses of 0·3 g., that the optimum dose of atebrin for all forms of malaria is probably 0·1 g. per 15 kg. body-weight per day for a period of six to seven days. At the end of this period a good deal of the drug has accumulated in the body and continues to be excreted for a further period of seven days or longer. The malarial parasites are thus probably subjected to the action of the drug for a longer period than the actual period of administration.

General progress of patients.—The two series of cases, treated with atebrin and with quinine, showed similar favourable progress as regards increase in hæmoglobin percentage and body-weight, also in the rate of reduction in the size of the spleen.

SUMMARY AND CONCLUSIONS.

1. Notes are given on 50 cases of malaria treated with atebrin, a new synthetic drug evolved by the makers of plasmoquine. Forty-six cases treated with quinine bihydrochloride were used as controls.

2. Atebrin compares favourably with quinine in ridding the blood of malarial parasites and in relieving symptoms. So far it seems superior to quinine in preventing relapses.

3. Atebrin is not unpleasant to take, but in a small proportion of cases it gives rise to abdominal pains. Where comparatively large doses are used, and excretion of the drug is delayed, a yellowish discoloration of the skin appears, which may remain from 8 to 15 days.

4. Atebrin, like quinine, does not affect the viability of the gametocytes of *P. vivax* or *P. falciparum*. Its use, however, over a period of seven days or less destroys the gametocytes of *P. vivax* with sufficient

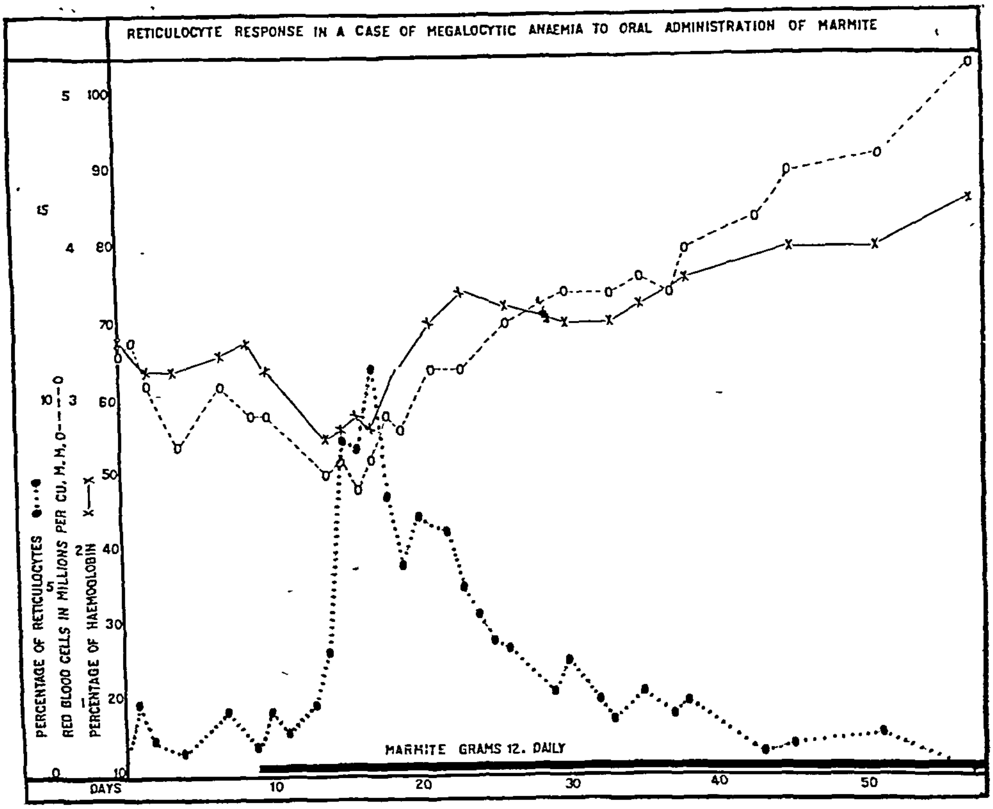
FIG. 2 (Case 1).



Progress under treatment.—She was given a low fat, high calcium diet, with the addition of calcium lactate (10 g.) and two tablets of Radiostol (British Drug Houses) daily. There was immediate improvement of the diarrhœa, and she began to pass only two stools a day. The tetany disappeared. Iron in large doses was given, but the anæmia remained unaltered for six months.

On Dec. 29th, 1931, she was admitted to a nursing home for intensive treatment of the anæmia.

Clinical examination.—Weight 6 st. 13 lb. Pale skin with malar flush and slight icteric tinge of conjunctivæ. Tongue raw with red edges. (To a direct question she answered that her tongue had often been sore.)

Special examinations.—Stools: total fat, 18·7 per cent.; unsoaped fat, 11·8 per cent. Sugar-tolerance test: fasting blood-sugar, 0·054 per cent.; blood-sugar after 50 g. glucose by mouth—in 40 minutes 0·076 per cent., in 80 minutes 0·075 per cent., in two hours 0·083 per cent., no glycosuria throughout. Serum calcium, 9·7 per mg. per 100 c.cm. Plasma phosphorus, 3·5 mg. per 100 c.cm. Plasma phosphatase, 0·182. Blood count: red blood-cells, 2,500,000 per c.mm.; hæmoglobin. 52 per cent.; colour-index, 1·01; white blood-cells, 2400 per c.mm.; polymorphs, 39 per cent.; lymphocytes, 58 per cent.; eosinophils, 1 per cent.; large mononuclears, 2 per cent.; reticulocytes, 1·7 per cent.; platelets scanty, great anisocytosis, no poikilocytosis. The mean diameter of the red blood-cells was 8·115 μ, the variability 11·7 per cent, and there was a megalocytosis of 37·2 per cent. giving a curve compatible with a diagnosis of pernicious anæmia (Fig. 3). The indirect van den Bergh reaction was 0·75 van den Bergh units.

TREATMENT.

In order to simplify the conditions of the experiment as far as possible during the initial period the patient was given no red meat, and no fresh fruit or green vegetables. Chicken once a day was allowed. To this was added 12 g. of marmite, usually taken cold. This was much disliked at first, but was soon tolerated. Daily blood observations were made. The reticulocytes started to rise on the sixth day, reaching a maximum of 17·2 per cent. on the eleventh day, and then falling slowly to normal. This was followed by a rapid rise in both red blood-cells and hæmoglobin (Fig. 4). Thirty-nine days later the red blood-cells were 4,000,000 per c.mm., hæmoglobin 78 per cent., colour-index 0·9. The indirect van den Bergh reaction was 0·2 van den Bergh units. Progress has continued, and the red blood-cells are now 5,200,000 per c.mm., hæmoglobin 88 per cent., colour-index 0·84. There is still a leucopenia, the white blood-cells being constantly between 2000 and 3000 per c.mm. The striking hæmatological improvement was accompanied, as in Addisonian pernicious anæmia, by an increased sense of well-being and by a gain in weight[29]—1 st. 3 lb. in 10 weeks, in spite of occasional attacks of diarrhœa lasting one to two days.

CHARACTER OF THE ANÆMIA.

Both cases showed a hyperchromic megalocytic anæmia similar to other reported cases. There was a striking absence of poikilocytosis, as was also noted by Blumgart[2] and Holmes and Starr.[16] The van den Bergh indirect reaction was low, varying between 0·5 and 0·75 van den Bergh units. Holmes and Starr also record a negative reading in the only one of their cases in which the examination was made, and lens; a few in the fœtal nucleus (Mr. C. Goulden). She was deaf, and examination of the ears showed bilateral adhesive catarrh of both Eustachian tubes with fibrous ankylosis of the left ossicles and two perforations of the left tympanum. The heart and lungs were normal. B.P. 110/70. There was slight distension of the abdomen. The liver was palpable 3 cm. below the costal margin on inspiration.

Special examinations.—Urine normal. Stools pale and porridgy in consistency. Total fat, 75·8 per cent.; unsoaped fat, 67·4 per cent. Serum calcium, 8·4 mg. per 100 c.cm. Plasma phosphorus, 3 mg. per 100 c.cm. Plasma phosphatase, 0·283. Test-meal: free hydrochloric acid, 0·27 per cent.; total acidity, 80. Blood count: red blood-cells, 4,000,000 per c.mm.; hæmoglobin, 62 per cent.; colour-index, 0·76; white blood-cells, 4800 per c.mm.; polymorphs, 67 per cent.; lymphocytes, 24·5 per cent.; eosinophils, 4 per cent.; large mononuclears, 4·5 per cent. Wassermann reaction negative. Urine normal.

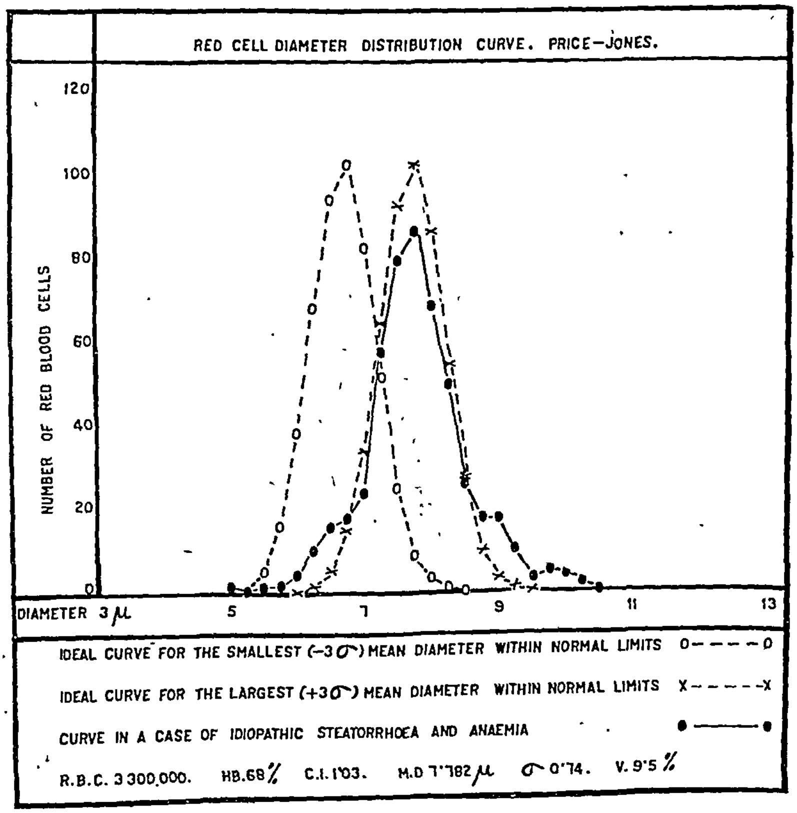
Course.—She improved on a low fat, high vitamin diet, together with calcium lactate 10 g. daily.

On Jan. 21st, 1931, she was readmitted to the London Hospital complaining of diarrhœa, weakness, dyspnœa, and palpitation.

Clinical examination.—Weight 7 st. 6 lb. Chvostek sign positive. Trousseau sign negative. Slight icteric tinge of conjunctivæ. Tongue smooth, papillæ pale and atrophic. Soft, light brown hair, with a tendency to silver grey. Skin dry. Large moist red abraded areas from 2 cm. to 8 cm. diameter on all limbs, and to a lesser extent on trunk. Many of these lesions showed scaly brown pigmented borders. One lesion on the left calf showed a deep brown scaly periphery and a moist red abraded centre.

Special examinations.—Stools: total fat, 39·8 per cent.; unsoaped fat, 15·6 per cent. No amœbæ or cysts seen in the stools. Agglutination reactions negative for typhoid and dysentery organisms. Blood-urea, 20 mg. per 100 c.cm. Sugar-tolerance test: fasting blood-sugar, 0·064 per cent.; blood-sugar after 50 g. of glucose by mouth—in 45 minutes 0·077 per cent., in two hours 0·08 per cent., no glycosuria throughout. Test-meal: free hydrochloric acid, 0·22 per cent.; total acidity, 80. Serum calcium, 8·4 mg. per 100 c.cm. Plasma phosphorus, 2·1 mg. per 100 c.cm. Calcium balance: the calcium output was estimated in the urine and fæces for three three-day periods. The patient was kept on a weighed diet of known low calcium content. The calcium output in the urine was much less than normal (0·04 g.); that in the fæces was double the normal (0·01 g.). Controlled radiograms revealed no abnormality in the bones examined. Examination by opaque enema showed a condition of megacolon in which four pints of barium sulphate were used, the whole colon being of poor tone and showing great enlargement of the lumen. Blood count: red blood-cells, 1,400,000 per c.mm.; hæmoglobin, 62 per cent.; colour-index, 1; white blood-cells, 3200 per c.mm.; polymorphs, 63 per cent.; lymphocytes, 27 per cent.; eosinophils, 3 per cent.; large mononuclears, 7 per cent.; severe anisocytosis, punctate basophilia, poikilocytosis. Indirect van den Bergh reaction, 0·1 mg. per 100 c.cm.

FIG. 1 (Case 1).



Course.—There was a rapid response to liver extract therapy, the reticulocytes reaching a level of 18·5 per cent. and the total red cell count 4,300,000 per c.mm. The patient did not take the liver extract regularly, and the anæmia relapsed. She was therefore readmitted for intensive treatment of the anæmia on Dec. 18th, 1931. Blood count: red blood-cells, 3,300,000 per c.mm.; hæmoglobin, 68 per cent.; colour-index, 1·03; white blood-cells, 2400 per c.mm.; polymorphs, 56 per cent.; lymphocytes, 39·5 per cent.; eosinophils, 3 per cent.; large mononuclears, 1·5 per cent.; platelets scanty, anisocytosis, no poikilocytosis, mean diameter of red cells, 7·782 μ; just larger than the largest calculated normal mean of 7·718 μ. The variability was 9·5 per cent. and there was 8·8 per cent. megalocytosis. The Price-Jones curve is shown in Fig. 1. The indirect van den Bergh reaction varied between 0·5 and 0·75 van den Bergh units. Urobilinogen not in excess in the urine

TREATMENT.

She was given a high calcium diet which contained meat and green vegetables and, in addition, 12 g. of marmite daily. Radiostol and calcium lactate were discontinued, to obtain as far as possible a pure marmite effect. Daily blood examinations were made. The reticulocytes started to rise on the sixth day, reaching a maximum of 10·8 per cent. on the ninth day, and then falling slowly to normal (Fig. 2). The red blood-cells and hæmoglobin rose steadily, the red blood-cells reaching a level of 4,000,000 per c.mm. 25 days after treatment was begun. They are now, 5,000,000 per c.mm., and the hæmoglobin is constantly in the neighbourhood of 80 per cent., while the indirect van den Bergh reaction is 0·25 van den Bergh units. The diarrhœa and tetany which previously had been controlled became extremely severe after radiostol and calcium were omitted, but despite this there was a gain in weight, and the improvement in the blood picture was no slower than in Case 2, where diarrhœa was not severe. The significance of this observation is discussed later.

CASE 2.—A single woman of 22 years, seen in consultation with Dr. D. S. Campbell, of Grimsby.

Clinical history.—She was an only child, and since babyhood had always had loose stools. They were pale, but not bulky or offensive. No blood or mucus was ever passed. She never had the energy to play games. Three years ago she began having attacks of diarrhœa every two weeks, when she passed as many as eight motions a day. She does not dare to drink hot food for fear of precipitating an attack. Unrelated to the diarrhœa she gets tingling and numbness.

S.sc. = Subicteric sclerotics. * Blood picture described by Adler as pseudo-pernicious anæmia of children.

should be facilitated, it appears more reasonable to conclude that marmite supplies or enables the body to prepare some principle essential to normal bone-marrow activity. These observations also suggest that marmite exerts its action upon the disordered hæmopoiesis alone, since other symptoms were unaltered.

RELATIONSHIP OF MARMITE TO THE PRINCIPLE IN LIVER EFFECTIVE IN PERNICIOUS ANÆMIA.

Marmite was without effect upon the hypochromic and erythroblastic types of anæmia occurring in association with cœliac disease.[1] Presumably, therefore, it exerts a specific action, as does the effective principle in liver upon some failure of hæmopoiesis resulting in a megalocytic anæmia. Such a statement raises the question of its relationship to this principle.

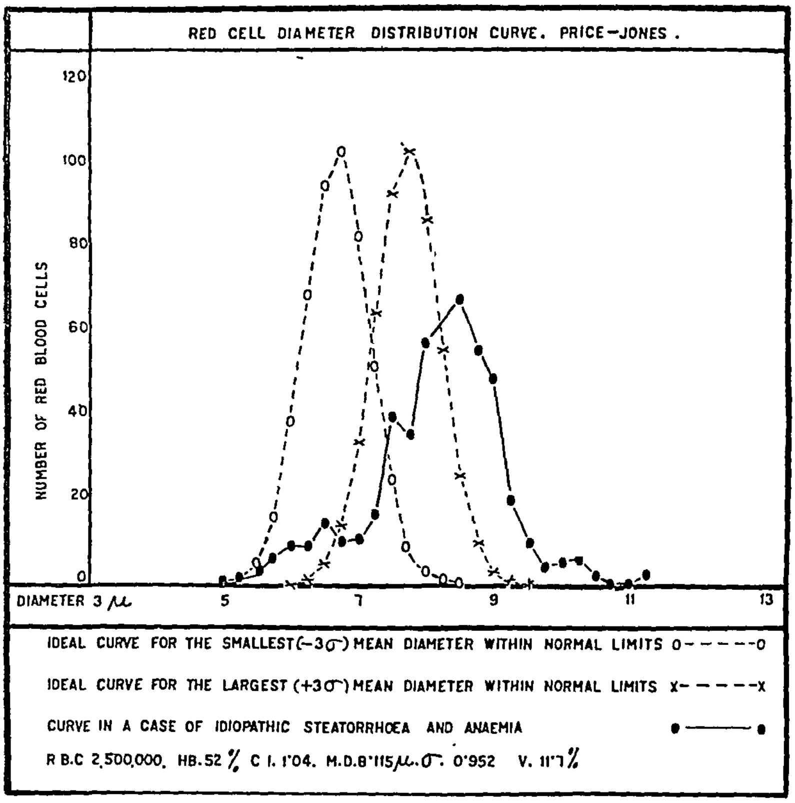
Case 1 had previously responded to liver extract with complete recovery of her anæmia. Two of the cases reported by Holmes and Starr[16] recovered when whole liver was given in addition to other therapeutic measures. The case reported by Witts[33] also improved on liver extract, which suggests that probably a factor common to both liver extract and marmite is involved. Marmite is a complex substance prepared commercially from yeast. It contains, therefore, all the constituents of the vitamin B complex, and small amounts of such things as celery seeds added for flavouring purposes. Liver extract is also rich in vitamin B.[11] Experimental evidence, however, as to the effect of the vitamin B complex upon hæmopoiesis is conflicting,[12 26 27] whilst clinically anæmia is not invariably associated with either of the conditions due to lack of vitamin B. If anæmia occurs in beri-beri[19] or pellagra,[3] it is almost invariably hypochromic in character.

Marmite, however, is useless in the treatment of Addisonian pernicious anæmia,[6] which suggests that though the substances effective in the treatment of the two anæmias are both present in liver extract they are not identical. It is clear that until further work has been done it is impossible to determine which element in marmite is concerned in hæmopoiesis, *and how it is related to the principles in* liver extract.

RELATIONSHIP OF THE ANÆMIA TO DIARRHŒA.

Diarrhœa.—Castle[5] and his co-workers in discussing the part played by disorders of the digestive tract in the ætiology of anæmia conclude "in general

FIG. 3 (Case 2).



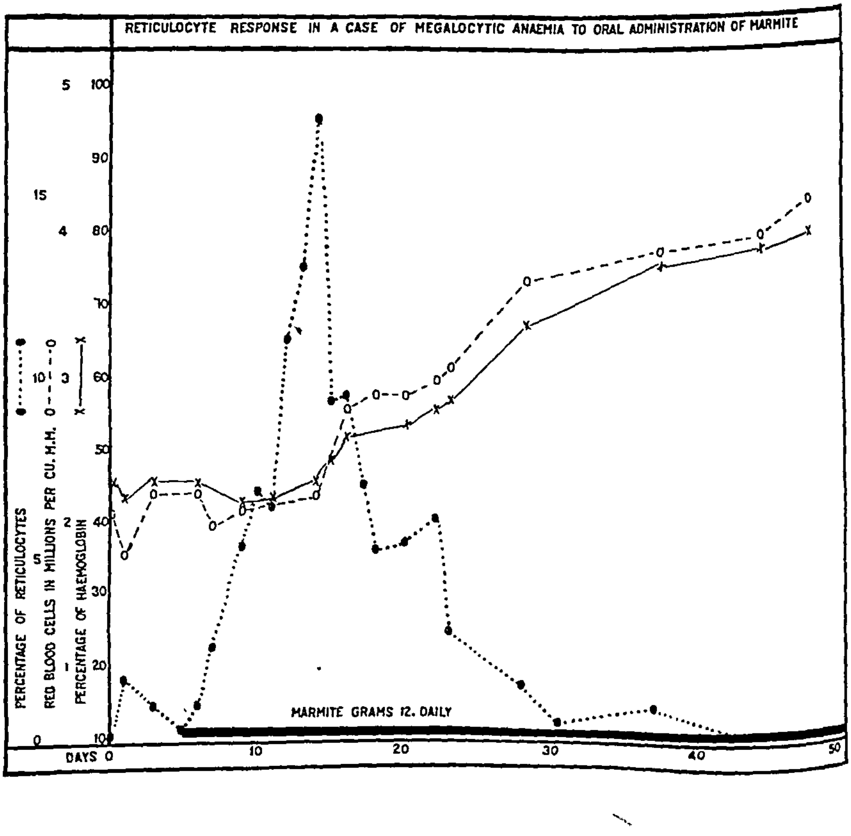
no comment is made except by Vischer[30] upon the presence of jaundice. Free hydrochloric acid was present in the gastric juice in both cases, and occurred in four of the nine reported cases where a fractional test-meal was done. Thaysen[28] believes that changes in the character of the anæmia occurring in the same patient are peculiar to cœliac disease. He, however, makes no attempt to correlate his blood findings with the effect of treatment. It is well known that certain cases of Addisonian anæmia require iron before the blood picture becomes normal, and also that spontaneous remissions occur without any treatment. The most dramatic changes in cœliac disease have been reported in children in association with sepsis, but again sepsis will precipitate a relapse in Addisonian anæmia. The anæmia, therefore, is in no way peculiarly polymorphic.

RESPONSE TO MARMITE.

In both cases the response of the anæmia to marmite was as dramatic as that obtained by the administration of liver extract in the treatment of Addisonian pernicious anæmia. Minot[22] and his associates have shown that in the latter, if maximum amounts of potent material are given, no serious complications being present, the height of the reticulocyte rise is inversely proportional to the level of the red blood-cells before treatment. In both cases the maximum reticulocyte level was in close accord with that calculated, suggesting that an adequate dose was given. In order to study its action uncomplicated by other drugs radiostol and calcium lactate were not given to Case 1. The blood picture returned to normal, and some weight was gained, though both the diarrhœa and tetany were severe until controlled by other means.

Theoretically marmite might exert its action either by favouring the absorption of, or actually supplying, some factor essential to hæmopoiesis. The blood-sugar curve in both cases, however, retained its characteristic flattened form despite recovery from the anæmia, and as long as radiostol was withheld, severe tetany and diarrhœa continued in Case 1. It is clear, therefore, that absorption of other essential substances is unaffected; and, since it is difficult to understand why the absorption of one factor only

FIG. 4 (Case 2).



CLINICAL AND LABORATORY NOTES

A CASE OF CEREBRAL TUMOUR.

BY F. CLAYTON, M.D. CAMB., M.R.C.P. LOND.,

ON. PHYSICIAN TO THE WARNEFORD HOSPITAL, LEAMINGTON.

ON July 25th, 1930. A. B., aged 22, was indulging n a day by the sea. He spent a good deal of the day in the water, but even more in sun-bathing on the eashore. In the afternoon he had a sudden attack of pain in the head, severe enough for him to consult a doctor, by whom the diagnosis of "heat-stroke" was made. From this time until admission to the Warneford Hospital six weeks later the headache never left him and it began to be associated with vomiting every morning and at varying times in the day. He also complained of double vision on looking to the right, five days before he came into hospital.

On admission he seemed in great pain, referred chiefly to the back of the head; he was quite sensible and showed no drowsiness. His right pupil was smaller than the left; both reacted to light and accommodation. No nystagmus. Right external rectus muscle weak. Tongue protruded slightly to the right. No facial weakness. No loss of power or loss of sensation in trunk or limbs. Deep reflexes all brisk and equal. Abdominal reflexes present; right lower abdominal definitely diminished. Plantar responses flexor.

Radiography of the skull revealed no abnormality. Ophthalmoscopic examination of the fundus oculi showed papillœdema of both discs, especially on the right side. The ears showed no evidence of anything pointing to intracranial sepsis. The cerebro-spinal fluid was under great pressure; there was no excess of protein, and the cell count was normal. The Wassermann reaction in cerebro-spinal fluid and blood was negative.

On Sept. 10th, 1930, a right subtemporal decompression was performed by Mr. Gordon Dingley. The trephine opening was enlarged to a diameter of three inches and on incising the dura the brain bulged through it under great pressure. The brain was explored but no tumour was discovered and the wound was closed. On the 11th headache and vomiting disappeared. On the 17th the decompressed area was bulging considerably and pulsating freely. No symptoms. On the 26th the patient was discharged with a large "hernia cerebri." There seemed to be some left facial weakness. The mental condition had become rather strange. It was then decided to use radium and on Oct. 13th, 1930, a Columbia paste helmet with 64 mg. was applied. The hernia was very tense at this time. The helmet was worn for 18 hours daily for a fortnight. The total amount was 19,406 mg. hours. On discharge from the hospital there was little change in the size of the tumour.

On Oct. 31st, however, it was softer and smaller, and on Nov. 20th it had disappeared.

From that time the condition of the-patient has steadily improved, and he is now able to carry on his ordinary work.

He has no headache and has completely normal vision. The optic discs are clear. The origin of the tumour and its nature are necessarily unknown. From the man's story there seems no doubt that his symptoms resulted from exposure to the sun. Similarly from clinical observation there is reasonable evidence for correlating the application of radium with the subsidence of the tumour.

DIHYDROMORPHINONE HYDROCHLORIDE (DILAUDID).

BY O. LEYTON, M.D. CAMB., D.SC., F.R.C.P. LOND.,

PHYSICIAN TO THE LONDON HOSPITAL.

THIS communication is in no way a clinical study of a comparatively new drug but has for its object its introduction to practitioners in Great Britain.

In THE LANCET of last year (1931. ii., 55) an article appeared entitled "The Heroin Habit" from which I may quote the following:—

> "The properties of heroin, which render it popular with some physicians, can in most if not all cases be efficiently replaced by other morphine drugs. For the relief of cough codeine is a valuable substitute. though not so strong as heroin; dicodid has as powerful an effect on the respiratory centre as morphine. though less than that of heroin, and its addiction properties are less pronounced than those of the latter drugs. For the relief of pain in patients in whom it is undesirable to act on the bowels, heroin is better than morphine but dilaudide offers the same advantages. This alkaloid has much the same type of effect on the respiratory centre as heroin but is weaker; it has about the same influence as heroin in its pain-relieving properties, and. like heroin, has little effect on the alimentary canal. Furthermore, the euphoric effects of dilaudide are weaker than those of both morphine and heroin as gauged by withdrawal symptoms."

There was a footnote that Profs. Dixon and Tiffeneau had had no experience of dilaudid.

This article aroused in me the desire to test the action of the drug upon some of my patients who were sorely in need of an analgesic. Since the preparation is a derivative of morphine, it is included in the list of substances controlled by the Dangerous Drugs Act, and therefore licences had to be obtained from the Home Office to permit importation of the drug by the London Hospital and a pharmaceutical chemist. These licences were granted without delay and I have now used the drug in a sufficient number of cases to permit me to arrive at a conclusion about its value as an analgesic but not to decide whether addiction develops.

The first case treated was one of thromboangiitis obliterans accompanied by severe pain which was not controlled by any of the many methods adopted, including injection of muscle extract, and necessitated injections of heroin four-hourly. I was faced with the dilemma and concluded that it was wiser to let a man of 75 develop a heroin habit rather than let him sink rapidly under fiendish torture. Heroin had been increased to gr. 1/6 four-hourly and since it was failing to give relief and a bigger dose of heroin may paralyse the respiratory centre morphine had replaced heroin and gr. ½ was being given at comparatively short intervals. Dilaudid gr. 1/30 replaced the morphine and gave relief for about four hours. The patient was quite willing that all the doses of morphine should be replaced except that given at 10 P.M. He stated that the dilaudid did not help him to sleep.

This patient had been under morphine and heroin for a comparatively short time. Another case seems to show that dilaudid cannot replace morphine when addiction has developed; for the patient who had a draining abscess of lung, and was taking morphine sulphate up to grs. 30 daily, was given dilaudid without any relief. A third case was that of a hospital nurse who suffered from tic douloureux. An injection of dilaudid relieved pain; it did not cause sleep but left her in a condition which allowed her to carry on her work.

The drug is not completely free from adverse effects, although nausea, when caused, lasts as a rule only a few minutes. One patient, however, a woman of about 60, who was suffering from severe pain due to arthritis deformans, vomited for twelve hours after an injection of dilaudid 0·002 g. This is the only case in which it has caused vomiting.

The drug failed to give relief in a case of what I believed to be "associated pain" or "memory pain."

I have used dilaudid in several dozen cases including pleurisy, sciatica, facial neuralgia, and angina pectoris with beneficial effects. Two cases it can be shown that patients with diarrhœa are more prone to develop anæmia than patients without diarrhœa." Thus Keefer[20] and his associates have recently found that the various types of anæmia which may be associated with tuberculous and dysenteric ulceration of the intestine improve when the diarrhœa is controlled. Lehndorff and Mautner[21] draw the same conclusion in the case of cœliac disease. A study of the present cases, however, suggests that the failure of hæmopoiesis is not dependent upon a deficiency brought about by loss of essential factors due directly to the diarrhœa, but rather to some associated but independent failure of absorption and digestion. Thus in Case 2 the diarrhœa was controlled for six months but the anæmia persisted until relieved immediately by the administration of marmite; while Case 1 was cured of her anæmia in spite of persistent diarrhœa. Certain cases with severe steatorrhœa, to be reported later,[1] have never shown any anæmia. Castle[6] and his co-workers have shown experimentally that such an associated but independent failure of digestion occurs both in chronic diarrhœa associated with intestinal anastomoses and in sprue.

RESPONSE OF OTHER SYMPTOMS TO MARMITE.

The pellagra-like skin lesions in Case 1 responded as dramatically as the blood picture to the administration of marmite. It is likely that this was due to the rich content of vitamin B_2. All other symptoms were unaffected.

RELATIONSHIP OF THE HYPERCHROMIC MEGALOCYTIC ANÆMIAS OF CŒLIAC DISEASE TO OTHER MEGALOCYTIC ANÆMIAS.

The question at once arises as to the relationship of this type of megalocytic anæmia to Addisonian pernicious anæmia and that occurring in sprue, in association with gastrocolic fistula, and in tropical anæmia. They are all hyperchromic anæmias with a marked shift of their red blood-cell distribution curve to the right of normal. They react to the effective principle in liver extract or its substitutes, and, except for a few atypical cases in children, fail to respond to iron. Addisonian pernicious anæmia differs from the others in the following ways:—

(1) The indirect van den Bergh reaction is always high, readings of from 2·0 to 5·0 van den Bergh units being common during a relapse.[7]

(2) Poikilocytosis is a feature of the stained film.

(3) Free hydrochloric acid is almost invariably absent from the gastric juice.

(4) The anæmia is unaffected by marmite.

In cœliac disease the indirect van den Bergh reaction is low. Similar low readings are recorded in sprue,[7] in tropical megalocytic anæmia,[31] and in anæmia associated with gastrocolic fistula.[8] The slight poikilocytosis of cœliac disease is also a feature of sprue[7] and tropical megalocytic anæmia.[31] Free hydrochloric acid is not infrequently found in all megalocytic anæmias other than Addisonian pernicious anæmia. Marmite has been shown to be effective in two cases associated with cœliac disease and in tropical megalocytic anæmia,[32] while it is valueless in the idiopathic form. It appears, therefore, that there is a large group of megalocytic anæmias, possessing certain features in common, which can be differentiated from Addisonian pernicious anæmia.

SUMMARY.

(1) Two cases of megalocytic hyperchromic anæmia associated with tetany and steatorrhœa are reported. (2) The anæmia was cured by the administration adequate doses of marmite, the other sympton being unaffected. (3) The anæmia appears to unrelated to the severity of the diarrhœa or oth symptoms. (4) The relationship of this type megalocytic anæmia to other megalocytic anæmi is discussed.

It is a pleasure to thank Dr. Price-Jones for kindness in determining the red blood-cell dist bution curves and the physicians of Universi College Hospital for permission to include abstrac from their notes in Case 1.

GLASGOW LOCK HOSPITAL.—The annual rep shows that in 1931 the average number of pati resident nightly was 72, as against 58 in 1930, w the average sojourn of patients benefited was 64 d compared with 51 in the preceding year. The dispens attendances were 19,871, as against 19,919 in 1930. greater number in residence is attributed not to any incr of disease in the community, but rather to a chang attitude on the part of the persons afflicted, and also the part of the public. The old feelings of secret fear open distrust are stated to be giving way to feeling confidence and hope—and the policy of spreading knowle which the hospital is pursuing is held to have justi itself.

OPHTHALMIC HOSPITAL OF ST. JOHN IN JERUSAL The report for 1931 states that there was a ma increase in the number of in-patients. There were operations and 75,423 attendances of patients who, ever, gave no more than £3 (Palestine) as thank-offeri Endowments produced only £P925, but the expendi was £P5,329, the bulk of the difference being provided the Order of St. John. The hospital has complied with the "almost Utopian regulations for the installa *of sanitary systems*" connected with the municipal wa supply of Jerusalem, but since the gravitation suppl "available only for a few hours every fourth day" scheme which last year cost the hospital £P104 is "l more than a nuisance." Prices in the city have r substantially, fresh meat by as much as 12 per cent.

one time it had been discussed whether sprue and icious anæmia were a single entity. All sprue s passed through a megalocytic phase unless were cured before that phase was reached. es of sprue treated with liver extract showed definite and sustained improvement, He cribed two cases. treated with intravenous hepa and Hepatex P.A.F. respectively, which shown no improvement until given liver ract. Another case of relapsing sprue had proved slightly on exhepa and considerably on a simplex, but the mean diameter of the blood-cells had remained large and the con- ion had relapsed. A transfusion was given, lowed by Ventriculin. but the patient had con- ued to go downhill. Subsequently there was a rked improvement on hepatex and liver extract, t the patient had since relapsed again and it peared probable that the anæmia would become lastic and fail to respond to any form of liver atment. A fourth case was known to have had peracidity in 1925; when seen a few years later, ffering from sprue, he had achlorhydria. The stric juice, however, showed slight peptic activity, d the condition was not, therefore, achylia gastrica the full sense. At first there was no rise in acidity llowing the injection of histamine, but as treatment oceeded a response to histamine developed and ter the stomach began to secrete acid spontaneously d in increasing quantities, until a normal curve was tablished. Tropical sprue was a gastro-intestinal sease characterised by defective gastric secretion and alabsorption of fat, glucose, and calcium in the nall intestine. Dysfunction of the small intestine as the essential lesion, and in this sprue differed ndamentally from pernicious anæmia. An additional iagnostic point was that in sprue the rise of blood-ugar in the glucose-tolerance test was delayed, and he delay became less as treatment progressed. In ernicious anæmia the glucose-tolerance test gave a ormal curve.

Dr. G. W. **GOODHART** discussed a series of cases f megalocytic anæmia which could not be classed s pernicious anæmia. He classed them, however, n the group of anæmias due to defective blood formaion and not in the group due to excessive blood lestruction. They had in common megalocytosis, high colour-index and leucopenia; all had failed o respond to liver extract, and had appeared to show certain symmetry in the Price-Jones curve. The irst case was clinically a typical pernicious anæmia; here were less than 2 million red cells, the colour-index was high, van den Bergh's reaction positive. There was, however, little anisocytosis though some megalocytosis. The case did not respond to liver treatment but improved on blood transfusion. When seen later the anæmia was definitely megalocytic in type; the variability was increased. The Arneth count showed a shift to the left: not only was there an absence of the hyper-mature polymorphs typical of pernicious anæmia, but the opposite condition was present—an excess of young forms. At autopsy the bone-marrow was found to be aplastic; he would be interested to know whether pernicious anæmia ever terminated in aplasia. The second case occurred in a girl of 19, who had been complaining of pallor, breathlessness, and attacks of severe abdominal pain and vomiting for 14 months. The van den Bergh reaction was negative; there was no acid in the vomit. She had previously been given liver treatment in St. George's Hospital and while there had passed a melæna stool. The attacks of pain and vomiting persisted in spite of the renewal of liver treatment. The Price-Jones curve showed a shift to the right, variability was increased; there were leucopenia and a shift to the left of the Arneth index. Intestinal obstruction was suspected. but she was too ill for operation. At autopsy there was no bony evidence of pernicious anæmia. but severe ulceration and necrosis, with polypoid masses, were found in the jejunum. and melæna was present throughout the large intestine. Dr. Goodhart referred to seven other cases showing similar blood pictures, one associated with ascites and a contracted liver; another with Hodgkin's disease following prolonged treatment with deep X rays; another with rectal and vaginal hæmorrhages; another, possibly a true pernicious anæmia, associated with chronic intestinal obstruction from tubercular peritonitis; another with a tuberculous cavity in the lungs; another associated with lymphosarcoma; and another with sprue. All showed a megalocytic anæmia generally with a high colour-index and smaller or greater increase in variability: the Price-Jones curve showed a shift to the right in every case, and appeared to be symmetrical in all except the case with the tubercular cavity in the lungs. The Arneth curve showed either a shift to the left or no change. He had thought at one time that a symmetrical Price-Jones curve might serve to distinguish pernicious anæmia from sprue, but this had not been borne out by experience. He asked whether the curve had been symmetrical in Dr. Fairley's case of sprue which had failed to respond to treatment.

TROPICAL MACROCYTIC ANÆMIA.

Dr. **LUCY WILLS** said that tropical macrocytic anæmia was seen most commonly in pregnant women, though it also occurred in men and non-pregnant women. Her remarks referred to the disease as seen in India, where it occurred as a rule between October and April, and attacked all communities. Most patients reported for treatment during the second half of pregnancy and if they survived delivery there was generally a rapid improvement, but the death-rate was high. even in treated cases. A satisfactory history regarding fever was hard to obtain; diarrhœa and vomiting had been described as typical by Balfour. but varied with the incidence of diarrhœa in the population; sore tongue was usually present. The anæmia was very severe; in 54 consecutive cases 32 had counts below one million when first seen. The death-rate among her cases had not been much improved by liver extract at first, because the patients reported so late in the disease, but subsequently when the value of marmite was established and when patients began to appear at hospital earlier, the death-rate fell considerably. The blood picture was that of a megalocytic anæmia with a few megaloblasts and normoblasts. The Price-Jones curve showed a shift to the right and increased variability; there were few reticulocytes and the white cell count was variable. There was no hyperbilirubinæmia or other evidence of hæmolysis, and the test-meal showed normal acid secretion. Before the introduction of liver therapy all treatment was useless, but patients could now be treated successfully with liver extract or marmite, a yeast extract. The distribution of the disease, and dietetic surveys. suggested that it was a nutritional disorder. Dr. Wills had found diet grossly defective throughout the city in a survey she had made in Bombay. Marmite was inactive in Addison's anæmia so that the curative factor could which are still under my care have precipitated this communication because I dread to think what their suffering would have been if dilaudid had not providentially come to their aid.

A young man suffering from severe diabetes mellitus developed acute arthritis of his knee, so severe that for a time it was no easy matter to decide that it was not due to osteomyelitis. Excruciating pain persisted for several weeks in spite of the usual analgesics and complete fixation. Dilaudid 0·002 g., to begin with four-hourly and later every six hours, made *life bearable*. This patient developed distinct euphoria after the injection, but no untoward symptoms have developed on reducing the dose after four weeks' administration of the drug.

The other case is one of actinomycosis of the abdomen. If dilaudid were not available this patient would have had to receive very large doses of morphine which would have led not only to loss of appetite but also to stubborn constipation. The dose in this case had to be 0·004 g. which caused transient nausea and giddiness. The patient's appetite is indirectly stimulated by the drug because he is unable to eat when the pain is severe. Some time before a meal is due he receives a dose which allows him to eat in comfort. In this patient too euphoria follows the injection. The dose has not had to be increased although it has been given for a number of weeks.

In Germany the drug has been given as a rectal suppository with good effects, but of this I have not had experience. From my observations I conclude: (1) unlike morphine, it is *not necessary to increase* the dose of dilaudid; (2) nausea, giddiness, and confusion may develop for a minute or two, very rarely for longer; (3) the drug does not cause constipation; (4) the appetite is not marred by the drug; (5) in some cases euphoria is induced.

As already stated, I have not used the drug long enough to decide whether addiction develops.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE.

SECTIONS OF TROPICAL DISEASES AND OF MEDICINE.

AT a combined meeting of these sections on April 7th the chair was taken by Prof. J. GORDON THOMSON, President of the Section of Tropical Medicine, and a discussion on the

Megalocytic Anæmias of Tropical and Non-tropical Countries

was opened by Dr. L. J. WITTS. Thanks to the work of Dr. Price-Jones, he said, it was possible to construct curves to show whether the cells present in an anæmia were larger or smaller than the normal red blood-cell, or, in other words, to show whether a megalocytic or a microcytic anæmia was present. When megalocytes were present in the peripheral blood there was a proliferation of megaloblasts in the bone-marrow, and this proliferation might be the result of either a megaloblastic degeneration of the bone-marrow—such as that believed to take place in pernicious anæmia and the tropical anæmias—or a hyperplasia designed to repair blood destruction. The anhæmopoietic anæmias fell into three groups: nutritional anæmia, including tropical macrocytic anæmia of pregnancy; gastrogenous anæmia, including pernicious anæmia; and alimentary anæmia, including intestinal anæmia, fatty diarrhœa, and pellagra. Pernicious anæmia was now believed to be essentially due to achylia gastrica; a principle normally formed in the stomach was essential to the development of normal blood, and where this principle was absent it could be replaced by stomach and liver extracts. The intestinal anæmias were often associated with defective diet, achlorhydria, and diminished absorption, and might develop following intestinal resection, or stenosis of the intestine—for example, stenosis due to tuberculosis—infestation with intestinal parasites, and gastro-intestinal ulceration. Fatty diarrhœa was not uncommonly associated with a megalocytic anæmia and was seen in such conditions as cœliac disease, sprue, chylous diarrhœa, pancreatic diarrhœa, and gastro-colic fistula. The anæmia tended to pass through three stages: hypochromic anæmia with normoblastic marrow; megalocytic anæmia with megaloblastic marrow; aplastic anæmia. The first problem in cases of fatty diarrhœa was to decide how far the anæmia was the result of impaired gastric digestion and how far it was the result of diminished intestinal absorption. In a high proportion of cases there was achlorhydria, and in some it had been shown that the gastric intrinsic factor might be absent although hydrochloric acid was present. In some, gastric digestion was normal, and in these the anæmia must be taken as being due to diminished intestinal absorption. In the achylic group the problem was to decide to what extent the anæmia was due to the absence of the gastric intrinsic factor, and to what extent it was due to the absence of the vitamin B complex from the diet.

Megaloblastic proliferation due to an attempt to replace rapidly destroyed blood-cells was an uncommon and obscure condition. In one hæmolytic infection (bartonella) megalocytic anæmia occurred; with syphilis and blackwater fever the anæmia was of the secondary type. A hæmolytic anæmia of pregnancy occasionally occurred in temperate zones and differed from the tropical anæmia of pregnancy. A similar acute hæmolytic anæmia might occur spontaneously in men. Most anæmias of this type were microcytic, but a few megalocytic cases had been described in which there was an increase in the mean diameter of the red cells, but rarely much anisocytosis. A case of aleukæmic leukæmia had been described in which the van den Bergh reaction was positive and megalocytosis, polychromasia, and hæmosiderosis were present, and four cases had been reported by Prof. L. S. P. Davidson in which the red cells as well as the white cells in the blood picture had been affected in patients with Hodgkins disease. He would like to repeat that the two main divisions into which megalocytic anæmias could be grouped were: those due to a megaloblastic degeneration and those due to hæmolysis. Cases in the second group were rare and obscure.

SPRUE.

Dr. N. HAMILTON FAIRLEY said that Oroya fever was the only tropical megalocytic anæmia of hæmolytic origin. The blood destruction was very rapid in this disease and the red cell count might fall to below a million in a few hours. In other diseases, such as blackwater fever, where there was rapid hæmolysis the bone-marrow always showed an erythroblastic hyperplasia and never a megaloblastic degeneration. The anæmia developing in tropical sprue was megalocytic in a large proportion of cases. The colour-index was usually in the neighbourhood of one, and the red blood count had been between 2 and 3 million at the initial examination in a large series of cases. The patient generally complained of intestinal symptoms orthopædics, heart disease in children, even cancer. He looked upon this kind of thing with serious misgivings, for the State was providing a series of watertight compartments; if the right sort of patient with the right sort of disease fell into the right compartment, he was treated well, but there was little to guide him there. What was needed at the present time was increasing coördination of medical practice—especially at the periphery. It was a disaster to exclude the practitioner from many of the schemes in the profession; for the sake both of the profession and the public a complete State medical service should be developed. In the past, much research work had been done in the big voluntary hospitals; this was not because the staffs of these hospitals had a different type of mentality, but because the conditions of work there were favourable. The profession would produce better results in research if it were unified.

It was unfortunate that the doctor was financially dependent on the patient; if he went to see a patient too often (in the patient's opinion), he was adjudged to want money; if he did not go often enough he was charged with being neglectful. It would make for better work if the doctor could speak freely to the patient without fear that as a consequence he would go to another doctor.

Some form of State service Mr. Hastings regarded as inevitable. Two courses were open to the profession: it could wait and do nothing, and then the politicians would suddenly wake up and would inflict some incomplete and undigested scheme, like the panel or something worse; or it could see what was coming and try to mould public opinion, so that when the change did come a service would be formed which would be advantageous both to the science of medicine and to the public generally.

Sir **Ernest Graham-Little**, M.P., recalled a meeting of the society two years ago when he had been asked to open a discussion on the relative advantages of contract and private practice. At that date a scheme for the absorption of the community in contract practice had been put forward by the British Medical Association to forestall, if possible, another scheme which it was feared the Socialist Government intended to rush through. For himself he saw little difference between the two schemes. The B.M.A. scheme envisaged an extension of contract practice which was to include the whole community. Mr. Hastings had not made it clear what sort of general practitioner the socialist scheme had in mind. Did it contemplate a continuance of panel practice or something different? What made the scheme more actual two years ago was the fact that the Socialist Government was in power; that was now no longer the case, and he did not think the danger was likely to be revived in the present generation. The proposals as he saw them were twofold: the part to be played by the general practitioner, and by the hospitals as medical service. Both were to be carefully looked into. Numerically medical men and women were a small section of the community; they could not settle matters in the way they would like; they had to make them acceptable to their masters, the public. Under the proposal just outlined the choice of doctor and of where to go for his treatment were taken from the patient; but the British public could not be forced to go where they did not want to go. In the past the poor-law hospitals—much older as they were than the voluntary hospitals—had never been able to earn anything like their popularity.

But was the medical profession as a body, he asked, so keen upon being converted into a body which would closely approximate to the position of civil servants—i.e., with whole-time medical officers under complete departmental control. If not, he did not think a State medical service was inevitable. To the question, Would it be to the advantage and for the progress of medicine? he would answer emphatically No. Nothing would so conduce to standardisation, for a State possessed neither soul nor mind. In a recent letter addressed to him a young practitioner remarked that the ideal of the Ministry of Health was the practitioner who kept prescribing down and records up. Was such the final aim of the Hippocratic art? Loss of independence and of competition would be a serious drawback in State schemes. Anyhow the cost would be prohibitive; no Chancellor for a long time to come would ask for an additional eleven millions of money. What then was the great advantage of the voluntary hospital system? Mr. Hastings admitted that most of the research had been done there. What distinguished them from State-controlled institutions? First, individual management. In London there were over 100 hospitals belonging to the old poor-law service, now transferred to the London County Council, the affairs of which were managed by a central committee of the council, few of whom could know much about the matters they controlled. Compare therewith last year's work at Charing Cross Hospital, a splendid vindication in the face of great financial stress. How long would it take a municipal hospital to bring about such new additions? Economy would not be secured by handing over private concerns to Government management; a business which became too big for personal attention went to pieces.

DISCUSSION.

Dr. G. C. **Anderson** (deputy medical secretary, B.M.A.) said he did not agree with either opener, though he went further with Mr. Hastings than with his opponent, because now that the State had provided a medical service for the country he felt sure it would be extended. The B.M.A. did not sketch out its scheme because it thought the Labour Government would bring in a State-salaried service; what it was then afraid of, and was still fearing, was that the medical service in this country might develop on wrong lines—that there would be an extension of the clinic system rather than of the panel system. He agreed that at present the general practitioner was being frozen out. For £1,500,000, which might be contributed by the insured persons themselves, a specialist service could be provided from which insured persons were entitled to benefit. He wished the general practitioner to have further opportunities of extending his knowledge by being taken into close association with hospitals in his area. The B.M.A. had attempted to make insurance practice approximate as closely as possible to private practice; that was, he believed, in the interests of the profession and of the community. The present panel system was infinitely better than the service existing previously. He was anxious to prevent practitioners getting into watertight compartments—i.e., attending clinics for one particular disease only. The profession required a wider outlook.

Dr. A. **Welply** (secretary, Medical Practitioners' Union) said the State had stepped in and this movement was sure to progress, whatever doctors might do. He would not exclude people who could afford to pay for their medical attendance; he would not be Cohn's anti-anæmia factor but was possibly some part of the vitamin B complex, though the evidence was not conclusive that this was so. She had been able to produce a similar anæmia in monkeys by feeding them on diets based on the diet prevalent among the hospital class of patient, and deficient in vitamins, proteins, and salts. The condition ended fatally, but in a few cases which were preserved subsequent feeding with marmite proved to be curative. Marmite was a source of vitamins B1 and B2, but experimental work, and the freedom of beri-beri patients from this anæmia would seem to exclude B1 deficiency as the causative factor; more work was necessary to determine the exact nature of the active fraction. She asked whether Dr. Fairley had tried marmite in the treatment of sprue, as good results had been reported from its use in Madras.

Dr. C. PRICE-JONES said that the chief importance of his curves was to estimate anisocytosis. Their second advantage lay in the fact that from the distribution of cells the mean cell diameter could be calculated; this had no correlation with the degree of anisocytosis, but the variability had, and was therefore important. In the third place the curves showed the relation of distribution of cells and of their mean diameter to those of normal blood, as calculated from the examination of 50,000 normal cells. The appearance of symmetry in a curve could not be accepted as its face value; it was rash to call a curve symmetrical unless a mathematical calculation had been made to decide the degree of symmetry. The variability was much more important than the mean diameter; in cases other than pernicious anæmia the variability was low. In dysfunction of the bone-marrow there was megalocytosis and extreme variability, but where all the cells were affected, for example, by a toxin, the variability was not affected and might be low.

Prof. M. J. STEWART (Leeds) mentioned some cases of trinitrotoluene poisoning seen during the war. The blood changes in these had usually been aplastic, but in one or two cases they were megaloblastic. In one girl of 18 with atrophy of the liver there had been repeated showers of megaloblasts into the blood; she had made a good recovery. He wondered whether the case of megalocytic anæmia associated with contracted liver, mentioned by Dr. Goodhart, might possibly have been a case of necrosis of the liver.

Dr. R. C. LIGHTWOOD said that pernicious anæmia was almost unknown in children though recently a few cases had been reported. There might be three reasons for this; possibly the stomach might be more effective in producing the factor which stimulated the bone-marrow, but this was unlikely as hypochlorhydria was quite frequently found in children; secondly, pernicious anæmia might depend on faulty absorption of this factor, in which case cœliac disease might be expected to produce pernicious anæmia; thirdly, there might be some difference in the bone-marrow of children, and certainly the marrow was normally more active throughout childhood. Among 39 cases of cœliac disease, three had been quoted as showing the blood picture of pernicious anæmia. The usual blood changes in this condition included secondary anæmia with a low colour-index and a high proportion of lymphocytes. The lymphocytosis was rather characteristic of the disease and very persistent, sometimes being present years after the patient had recovered.

Dr. JANET VAUGHAN referred to 13 cases of cœliac disease treated with marmite. These are mentioned in an original article on p. 829.

In replying, Dr. FAIRLEY said that the curves in sprue had an appearance of symmetry more marked than that of pernicious anæmia curves, but that he would hesitate to regard them as more symmetrical without further calculations. He had not yet made use of marmite in sufficient doses in sprue to have formed any conclusions about its effects.

PADDINGTON MEDICAL SOCIETY.

A MEETING of this society held on April 12th, under the presidency of Dr. SWIETOCHOWSKI, was devoted to a discussion on

A State Medical Service.

Mr. SOMERVILLE HASTINGS said his wish was that everybody, without consideration of ability to pay, should receive in illness the best attention which medical science could give; he also wanted to see more prevention in medical arrangements. He was not advocating the scheme put forward two years ago by the British Medical Association, though it might constitute a useful step in the right direction His aim was a State service complete, unified, and free. He would have no compulsion for patient or doctor; he wanted a service so good that people would readily avail themselves of it. The doctor would be given freedom in medical matters; his routine clerical work would be done for him. Such a scheme should appeal to the most socialistic of all the professions, for, he said, doctors more than any others practised socialism. Their discoveries were, by tradition, broadcast to the world, and their charges were made according to the means of the patients. A desirable extension of the latter principle was that people should pay for medical services not in hard cash, but in rates and taxes, which were based upon individual means. During the last 50 years the general practitioner had been continuously robbed of clinical material and of interest in his work. Though he might diagnose infectious disease, the treatment was carried out at a fever hospital. Successive enactments had taken away from the general practitioner the diagnosis of one group of cases after another: tuberculosis he now saw less of than formerly, venereal diseases were treated largely in the clinics, and the treatment of school-children had been taken from him; there were also maternity and child welfare centres. In 1927 the *British Medical Journal* said: "There are no fewer than 17 departments, spheres, or directions of clinical activity for which provision is made in this sectional way under the auspices of local authorities; some of these cover an extensive field of medicine." Further, as soon as a patient got into a hospital the general practitioner lost all contact with him. Such were the complications of disease that many more cases were now going into hospitals than formerly, and many of the hospitals were now charging fees. Municipal hospitals were developing side by side with the voluntary hospitals; and because they had the financial backing of the State, and often controlled a bigger area, and so could arrange their clinical material in the way they desired, they were developing into formidable rivals to the voluntary hospitals. The process of providing medical needs by coöperative methods would go on and increase. A strong case could be made out for the treatment of the pre-school child, for the treatment of the adolescent before he came under National Health Insurance, and also for the treatment of all sorts of diseases in special clinics: rheumatism,

REVIEWS AND NOTICES OF BOOKS

What Life Should Mean To You.

By ALFRED ADLER. Edited by ALAN PORTER. London: George Allen and Unwin, Ltd. 1932. Pp. 300. 10*s.* 6*d.*

THE tale of literature devoted to Individual Psychology—the theory and practice of Dr. Adler and his friends—grows apace. Dr. Adler's own contributions, during the last few years, have been more than considerable, and may perhaps not unfairly be said to be, in form and quality, at once as baffling, as disarming, and as easily misjudged as is his personality.

Briefly put, Dr. Adler's published works fall into several groups which deserve to be distinguished, the one from the other. The first of these includes the "Organ-Inferiority," the "Neurotic Constitution," and the "Individual Psychology": books written in a not too easily understood German, and for the most part translated none too well, into an even less easily understood English (we had almost said, and perhaps with justice, American) between 1914 and 1924. The successive appearances of these books—some of them collections of essays—marked stages in the development of Individual Psychology, in the technical and scientific sense. In them the fundamental theses of organ-inferiority, the inferiority-sense, the prototype, the neurotic compensation, organ-jargon, and so on, were expounded in close technical terminology and were brought into relation with the classical psychological syndromes or reaction-types as illustrated by case-histories. These works remain indispensable for the professed adherent to Individual Psychology, and for the student of Comparative Psychology.

The books making up the second group (or, marking a second period) are perhaps rather hastily constructed volumes, of American provenance, easily read and pleasant, but discursive, and even formless, consisting in the main of the material from lectures and talks, taken down at the time, and revised for publication by friends and pupils. Among these must be reckoned the "Science of Living," "Understanding Human Nature," and the "Pattern of Life." They are frankly written in terms to be "understanded of the people," and are not necessarily the worse for that. Their engaging simplicity, their naïveté, and the apparent banality of some passages (in spite of the flashes of devastating epigram with which they are brightened) have led to their being under-rated in the mouths of many who confuse dullness with profundity, and simplicity with stupidity. And this, in its turn, has naturally led to a belittlement of Individual Psychology as a serious discipline. But the error of these fallible critics is that of those who have deemed "Alice in Wonderland" merely comic.

In a third and smaller group of volumes, Adler during the last few years has reinforced the links between Individual Psychology and the clinic. In "Problems of Neurosis," and again in the "Case of Miss R.," he has discussed the definite clinical problems of psychoneurosis, of obsession, and the like, in a truly Socratic fashion that is of the utmost help to practising psychologists as well as to many patients. In the present volume, however, a different note is struck. We may surmise that the substance was originally delivered in lecture form—perhaps in America where it was first published—but we are told that it has been edited by Alan Porter, and it is not difficult to recognise the skilled Oxonian hand of the poet, psychologist, and man of letters that we know him to be. The result is that, in despite of a title that is too journalistic, we have a really complete and almost systematic setting out, for the first time, and in agreeable literary form, of the general position taken up by Dr. Adler. The old doctrines that lie at the foundation of his recent constructive thought have been restated, and there is due insistence on recognition by the physician, the pedagogue, and the philanthropist alike, of the need for coöperation, in the social as well as in other fields. The orderly arrangement of the chapters, and the gently progressive method of exposition adopted, make this book an admirable one for perusal by the uninstructed practitioner, who will find benefit in a rapid conspectus before proceeding to closer study, and who wishes to recommend a book to his friends and patients. But, this being said, it still is true that, for those who desire really intimate acquaintance with the technique of Individual Psychological Practice, with the special attitude of Individual Psychology towards the sexual problem, and with the full metaphysical and philosophical implications of the whole theory, recourse must be had to the English versions of the three admirable treatises by Erwin Wexberg, of Vienna, and to the smaller books by Philippe Mairet and other English Individual Psychologists.

That Individual Psychology has "come to stay" will hardly, we think, now be disputed. Dr. Ernest Jones has recently admitted that it constitutes perhaps the best, if, indeed, not the only scheme of psychology available for the general practitioner. It is true that he added that this is perhaps less flattering to the medical profession than some might wish it to be. But the admission is important. It was recently said that Individual Psychology stands towards Freudian Psycho-Analysis much as does aseptic surgery towards the old Listerian system, with its paraphernalia of carbolic putty and steam sprays. The analogy may be pressed. Asepsis is now as integral a part of surgery as the disciples of Adler hope that Individual Psychology will come to be in medicine. Like asepsis, too, Individual Psychology is exposed to disparagement. The one was despised as "mere cleanliness"; the other is sometimes contemned as "mere common sense." But, if clean and common sense, why not? Cleanliness and common sense are each of the greatest pragmatic value and are justified alike by the deepest philosophy and the highest science! Again, asepsis and Individual Psychology are subject to like dangers. Insistence on ritual may crystallise into inelastic formalism; but neglect may slide into sloppiness or positive harm. So, at present, Individual Psychology is compelled to face, on the one hand the Scylla of academics, so dreaded by Nietzsche, and, on the other, that Charybdis of refusal to organise and to coöperate which drew Nietzsche to his solipsistic end. The essence of Individual Psychology lies in its freedom to adapt. As Einstein has said, it is the psychology of relativity. It has certainly brought relativity into the psychological field. Now, a psychology which can claim the author of the Special and General Theories of Relativity among its adherents can hardly be dismissed so lightly as may think some of those who chuckle over, without understanding, his own take in every person, irrespective of income. The scheme would naturally embrace 88 per cent. of patients, and legislation for the remaining 12 per cent. would cost a large amount of money, which would be saved by making the scheme all-inclusive. Even under a State service there would still be the private doctor, who would still be able to earn a living. Mention had been made of wastage in municipal hospitals, but he questioned whether there was more waste in them than in voluntary hospitals, which he had long thought employed the most wasteful machinery he had ever seen.

Dr. C. L. BATTESON (secretary, London Panel Committee) said he was opposed to a State medical service, for he thought it neither good for the community nor for the doctor. It was not necessary at the present time to provide full treatment for everybody. He did not think a State service was likely to come in the next 20 years. The only advantage to the public would be that of receiving treatment without making a direct payment. Moreover, under a State service the private practitioner would be gradually squeezed out. Dr. Batteson could not imagine a State service in which there would be any amount of free choice; and such a service would tend to stereotype the work of the profession and to stifle initiative. Also under a State service he did not think salaries would be princely. The price which would have to be paid for the loss of liberty and freedom of action would be too great.

Mr. W. MCADAM ECCLES agreed that service as good as that in the voluntary hospital should be at the disposal of everyone, but he did not agree it was necessary that this service should be under the State. It was difficult to define exactly what was meant by a voluntary hospital, because, so far as the staff was concerned, there was not now the voluntary service that there was 25 to 30 years ago; at St. Bartholomew's the staff had long ceased to be voluntary, for its members were salaried and dismissable at the end of any year. The most important feature of the voluntary hospital was its elastic administration. Moreover, the municipal hospital was only supposed to serve the people in the area of its own administration; and a further important point was the consultative nature of the voluntary hospitals. In this respect at present the municipal hospital was not as perfect as it might be.

Dr. A. BALDIE said that the matter was one of social tendencies—not of party politics or professional prejudice. The tendency to be always looking to the State for support was one fraught with danger to the State, the profession, and the public.

Dr. GERALD SLOT pointed out that in London there were 15,000 voluntary hospital beds, and 80,000 beds in municipal hospitals for the accommodation of the sick poor of London; hence it could be said that the municipal hospitals were doing the bulk of the treatment. People going to the voluntary hospital were seldom seen more than once by the same doctor or surgeon.

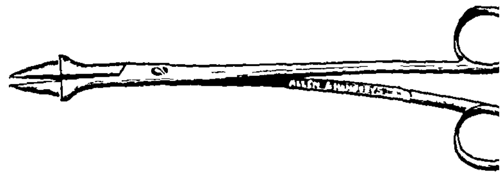
Dr. W. G. BENDLE laid stress on the need for giving the practitioner more clinical interest. Much of the treatment in voluntary hospitals was given by very junior men, though theoretically under supervision; the standard of qualification of the staffs of municipal hospitals was relatively higher because they were required to have filled a number of previous posts.

Other speakers were Drs. GIBSON, MELLOTT, STUNGO, FENTON, GRAY, and COHEN, and both openers briefly replied.

NEW INVENTIONS

A NEW TONSIL ABSCESS FORCEPS.

THE instrument here illustrated is designe
the opening of quinseys, and has the follo
advantages: (1) the point is sharp so that it
forates the overlying tissues easily and comparat
painlessly; (2) the edges passing down to the f
are sharp, though not razor sharp, thus cutting r



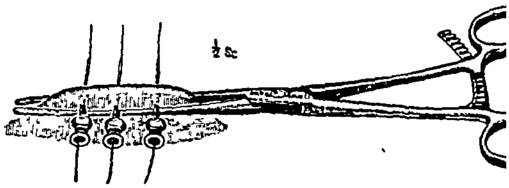
than tearing the tissues when the forceps is op
(3) there is a flange which takes the place o
old-fashioned strapping wrapped around a s
to prevent a too deep penetration; and (4) the
is slightly curved so that the hand does not int
in the line of vision.

The instrument, which has been made for n
Messrs. Allen and Hanburys, of Bethnal
London, has proved itself simple, satisfactory
relatively painless in use.

E. MILES ATKINSON, M.B., F.R.

BIOPSY AND SKIN GRAFT FORCEPS

THE purpose of this instrument is to remove
skin strips for grafting chronic ulcers of th
or ulcers due to burns by burying seeds or
below the granulations. This small operati
generally done without assistance in the out-p
department, and is accomplished expeditiousl
bloodlessly with the help of these forceps.
area from which the skin is to be remov



first anæsthetised by infiltration, three hypod
needles (No. 16 or 23 s.w.g.) are then passed th
as shown in the illustration. The strip of s
now pinched up and steadied with the forceps
underneath the needles, and can be shaved of
scalpel or scissors, all oozing being controlled
pressure of the forceps. The wound is conven
closed by threading fine silkworm gut or hor
through the hypodermic needles before withd
them. The forceps resemble ordinary sinus f
except that a rather long ratchet is incorp
in the handle. In addition to the ordinary u
which sinus forceps are put, the instrument is
for holding the vein on the stretch in the ope
of ligation of a varicose vein through a small in
The removal of small skin tumours and of sa
of skin for biopsy is much facilitated by usin
instrument.

The instrument has been made for me by
Down Bros., Ltd., St. Thomas's-street, London

The Ounce of Prevention

PNEUMONIA can often be prevented by the prompt and energetic treatment of bronchitis and influenza.

Notwithstanding the satisfactory results obtained by modern therapeutics and, in spite of all progress, mortality is still high. In a great number of cases pneumonia is the result of bronchitis, or of influenza, or, even, of a slight infection of the upper respiratory tract.

Antiphlogistine Dressing, applied at the onset, relieves the congestion, stimulates the superficial circulation, favours phagocytosis and, by re-establishing a normal circulation in the bronchi and alveoli, will help to prevent pneumonia from following an attack of bronchitis or of influenza.

bon mot: that Adler is the Sancho Panza to Freud's Don Quixote.

We commend this book heartily, but as a beginning and not as an end of studies in Individual Psychology.

F. G. C.

Nutrition and Physical Fitness.

By L. JEAN BOGERT, Ph.D., Formerly Instructor in Medicine, University of Chicago. London: W. B. Saunders Co., Ltd. 1931. Pp. 554. 14*s*.

THE arrangement of material in this volume is unusual. The reader is first introduced to a study of the characteristics of the common foodstuffs and the food requirements of the human being; the physiological processes connected with the absorption and metabolism of foods and the disposal of waste material are then dealt with; and finally, the methods of dietary planning are explained as they affect human beings of all ages, including those in normal health and those suffering from various disturbances of nutrition. The author provides a great deal of useful information and displays a worthy restraint in the handling of his material. The language is not technical and suggests that the lay public is the target at which the book is aimed. The average Englishman might benefit considerably by putting into practice the principles of nutrition upon which emphasis is laid, although it is doubtful whether he could easily be persuaded to read the whole of this useful work.

The Search for Man's Ancestors.

By Prof. G. ELLIOT SMITH, M.A., M.D., D.Sc., Litt.D., F.R.S. No. 16, The Forum Series. London: Watts and Co. 1932. Pp. 56. 1s.

THIS little book, the latest of a series of monographs by various authorities, is, like the others, a wonderful shillingsworth. Prof. Elliot Smith's name on the title page makes the detailed facts stand beyond question, but the interest is carried further than the actual specimens concerned. These, it might almost be said, are incidental in the story, for he has never lost sight of the object of the book, which is to give the narrative of the how and why of the several findings. It seems incredible that one should sally forth on the face of the earth to some chosen spot, where one has assumed that somebody may have lived and died about half a million years ago, more or less, that one should then dig or delve there with the intention of finding his remains—and that one should find them. Yet something like this has taken place, and these old proto-human fossils have been brought to light. Those who wish to gain some idea of how this has been done cannot do better than buy this booklet; they will not regret the purchase.

Transactions of the American Association of Genito-Urinary Surgeons.

THIS volume (XXIV., 1931) opens with two accounts of Solitary Cysts of the Kidney, a condition that was previously regarded as rare but now seems to be commoner than has been suspected. The first description treats of cysts into which extensive hæmorrhages have taken place, the second of old cysts whose walls have become calcified. In most cases of this sort there is a clear history of previous injury, and Dr. J. A. C. Colston expresses the opinion that wherever there is reason to suspect trauma of the kidney it should be explored. Hæmatomata can then be dealt with, and the risk of transformation into a cyst with subsequent adhesions and calcification can be eliminated.—Drs. D. W. MacKenzie and Allan B. Hawthorne discuss the rare condition of Hæmangioma of the Kidney, and report two cases.—Dr. F. R. Hagner deals with Angioneurotic Hæmaturia. He believes that if these cases are followed to their end many of the patients will be found to die of cardiovascular lesions associated with nephritis.—Drs. H. Cabot and W. W. Holland enter a plea for the more frequent use of nephrostomy, either as a temporary measure to tide over a crisis, or as a permanent remedy for an incurable condition. They describe the technique which they have employed, which is a modification of that advocated by Marion.—Dr. J. I. Farrell has studied the secretion of the prostatic gland in dogs by making a prostatic fistula.—The volume also contains many other interesting papers.

British Journal of Children's Diseases.

To the January–March number Dr. George W. Bray contributes a paper on the Allergic Child, in which he first discusses hereditary disposition which can be demonstrated in from half to two-thirds of all cases, and then the acquisition of sensitisation in those cases in which no definite hereditary influence can be detected. The common characteristics of allergic conditions are described, as well as the common individual manifestations of allergy in childhood, of which the most frequent are cutaneous eruptions such as eczema, flexural pruritus, urticaria and purpura, abdominal conditions, such as food upsets, colic, and recurrent vomiting, hay-fever, migraine, enuresis, and reactions to therapeutic sera and physical agents.—In their paper on Examples of Anæmia of Various Kinds in Children, Dr. F Parkes Weber and Dr. E. Schwarz describe examples of the following different types of anæmia: (1) severe anæmia cases of agranulocytic or aplastic type which turn out to be really of the nature of lymphatic leukæmia; (2) recurrent epistaxis with anæmia and temporary slight splenomegaly; (3) temporary anæmia probably due to lead; (4) anæmia associated with signs of colitis and enlargement of the liver (5) severe secondary or chlorotic type of anæmia probably of nutritional or dietetic origin; and (6 Lederer's acute hæmolytic anæmia.—In a paper on Chronic Streptococcal Toxæmia, Dr. J. D. Hindley Smith, who reports six illustrative cases, states tha this condition is far more widespread than is a present recognised, and appears to be on the increase especially in large centres of civilisation, so as to b almost as great a menace to national health and economics as tuberculosis. Three distinct stage may be described—viz., a primary in which ther is an infected local lesion; a secondary, characterise by general disturbance of the organism; and tertiary, in which localised damage takes place owin to the defensive reactions of the tissues.—In a pape on the Treatment of Early Cases of Knock-knee an Bow-leg in Children, Dr. Edgar Cyriax shows tha some of these deformities are primarily due to los of equilibrium between certain groups of muscle in the thighs, which cause faulty attitudes of th legs, and that early cases can be cured by mechan therapeutics to restore the loss of balance. In earl knock-knee treatment should consist in re-education Recourse is to be had to the so-called resisted exercise applied according to the Swedish system of Ling followed by stimulatory *pétrissage* to the weakene muscles, the others being left alone. In bow-le the weakened adductors of the thigh should b similarly re-educated by means of resisted exercise and subjected to stimulatory *pétrissage*.—Dr. W. F Bett reports an unusual case of multiple lipomat in a boy aged 2 years, which was successfull treated by operation.—The abstracts from curren literature are devoted to diseases of the blood an spleen.

THE LANCET.

LONDON: SATURDAY, APRIL 16, 1932.

ISIBLE "ULTRAMICROSCOPIC" VIRUSES.

THE conception of a visible filtrable virus is new one. Twenty-eight years ago Borrel scribed minute bodies in the virus inclusions fowl-pox which he considered to be the virus. the following year von Prowazek demonstrated nilar structures—termed by him "elementary dies"—occurring within and without the cells vaccinial lesions, and in 1906 E. Paschen ew attention to the minute granules in variolous mph and vaccinial material, commonly referred now as "Paschen bodies." He found somewhat milar granules in varicella, and from a detailed udy of these bodies, more particularly those esent in the variolo-vaccine lesion, concluded at they were specific. Since that time many vestigators have followed these pioneers in this eld. The original observations of Borrel and 'aschen have been confirmed and extended o other members of the group of filtrable viruses; ut, despite this, the view that some, at any rate, f the filtrable viruses are minute coccus-like nicro-organisms has not received general acceptnce. There have been several reasons for this ttitude. The technique required for the staining f elementary bodies is, relatively speaking, aborious and one which does not always furnish uccessful preparations even when carried out with great care. Added to this, artefacts, closely simulating elementary bodies, appear from time to time in such preparations to confuse the issue. But although these technical difficulties have probably delayed the recognition of the true nature of these elementary bodies, a much more effective brake on progress have been pronouncements by those speaking with authority. Evidence obtained from ultrafiltration experiments, which would not have been considered seriously were it not for the reputation of their authors, suggested that the disparity in size between virus and elementary body precluded any relationship. Expert microscopists have looked askance at these elementary bodies; in fact, at the discussion on filtrable viruses held by the Royal Society three years ago, Prof. J. G. G. Ledingham alone upheld the possible ætiological significance of the Paschen body in vaccinia.

During the last two years, however, events have moved rapidly and the specific nature of some of these elementary bodies has been placed beyond all reasonable doubt. C. E. Woodruff and E. W. Goodpasture[1] have shown that a single Bollinger body—the inclusion body of fowl-pox—when isolated and washed free from any adhering virus is still capable of infecting, and that the contents of the Bollinger body consists of numerous elementary bodies (the Borrel bodies) embedded in a gelatinous matrix. And the ætiological significance of the Borrel bodies has been further advanced by Ledingham who recorded in our columns last September that by fractional centrifugation he had succeeded in obtaining these bodies in relative purity and in demonstrating their specific agglutination with an anti-fowl-pox serum. Elementary bodies are present in psittacosis material, an observation first made independently in 1930 by W. Levinthal, R. D. Lillie, and A. C. Coles. These bodies stain easily and look like micro-organisms and on the strength of this and their more or less constant presence in virulent material Levinthal[2] concluded that they were the causal organism and proposed the name *Microbacterium multiforme psittacosis*. His conclusion was not justified, but the additional evidence required to prove his thesis has now been supplied by S. P. Bedson.[3] The latter has shown that the elementary bodies present in a suspension of virulent mouse-spleen can be freed from adventitious material by fractional certrifugation and washing and that the purified bodies which are capable of transmitting the disease are agglutinated specifically by an anti-psittacosis serum. In a like manner the original claim of Paschen, that the minute bodies described by him in vaccinia are the virus, has found confirmation. Applying similar methods to those employed by him in the case of fowl-pox virus, Ledingham (loc. cit.) has shown that the Paschen bodies are specifically agglutinated by an antivaccinial serum. E. G. Nauck and Paschen[4] have found that increase of virus in tissue culture is accompanied by a corresponding increase in elementary bodies, and finally, as they report on p. 823, Dr. G. H. Eagles and Prof. Ledingham succeeded in obtaining the Paschen bodies in a pure state by high-speed centrifugation and repeated washing and have shown that virulence resides entirely in the Paschen body.

Quite apart from the stride forward which these investigations mark in the study of filtrable viruses there is a point which calls for special comment, and that is that this progress has been achieved by the use of conventional methods alone. No sensible person would dream of decrying technical improvements and innovations. Refinements in dark-ground microscopy and the use of short wave-length light should prove of inestimable value in this field, especially in the case of viruses—and we know of several already—which are beyond the limits of microscopic visibility. But among the less-studied filtrable virus there must be some capable of investigation by the methods which have proved fruitful in the case of vaccinia and psittacosis, and the encouragement given by these successes should be of material help in the work lying ahead.

assical operations with a maternal death-rate 1·9 per cent.—a result to be regarded as extremely ood when it is borne in mind that the series ncluded all comers. In 24 cases premature labour ad been induced instrumentally before operation no mortality); in eight, forceps had been attempted 1 death); 14 were cases of eclampsia or other oxæmia (1 death); five were cases of accidental æmorrhage (1 death); and there were 25 cases of lacenta prævia (no death). H. R. SPENCER has eported [6] 120 cases, many of which were infected efore operation, with four deaths. This should e compared with the 1·23 per cent. mortality at he Chicago Lying-in Hospital in 895 cases of the ow-segment operation.

To sum up. While it may be granted that in nfected cases the newer operation is attended vith certain advantages that more than compensate for its greater difficulty, it is certain hat if the patient is not in labour the difficulties are much increased. No doubt a true ow-segment operation can be carried out at that period; only in 57 per cent. of GREENHILL's series was the patient in labour before the operation was started. But the lower segment is then imperfectly formed; it is not thinned out as it is after labour has been in progress for some time, and it is in consequence more vascular. Further experience of the operation at this stage is necessary before its value can be finally assessed.

◆

THE CINEMATOGRAPH IN MEDICINE.

THE cinematograph is as much a feature of modern civilisation as the motor-car and the aeroplane. For many years it has held a recognised place in general education, and instructional films of a high degree of excellence, portraying primitive peoples, features of animal and plant life, and the natural and architectural beauties of foreign countries appear to be an acceptable part of the programme in the usual places of entertainment. Films have proved valuable in disseminating information about modern agricultural methods, and the means of combating the various pests that attack crops and cattle. But the application of similar methods to medicine has been somewhat slow, and it is only within the last three years that the cinematograph has become a regular feature in scientific discussion and in the lecture theatres of medical schools. The reason is partly because medical education demands, perhaps more than any other, direct demonstration and personal guidance, partly because medical cinematography has not yet found its best methods.

The cinematograph has potentialities lacking in any other method of representation. It not only portrays form and motion, but through motion registers the dimensions and texture of the objects it records. It embalms the rarity; instances of rare diseases, or exceptional examples of more common ones, can be preserved for the study of successive classes. It bridges spaces of time, so that succeeding phases of some condition that may take months or years to develop may be shown in rapid sequence on the screen, allowing those who have only seen parts to visualise the whole, and all to form a coherent picture of what have been scattered glimpses. It provides an analysis of movements either too rapid or too slow to be appreciated by the eye. Accelerated photography, which shown at normal speed gives the slow motion film, permits the study of such subjects as normal and abnormal gaits, and the demonstration to students of the correct methods of tying ligatures and handling instruments. The division and growth of cells in tissue cultures, and the stimulating or retarding effect of drugs or radiation on this growth, may be recorded by retarded cinematography and projected at a speed that makes the process simple for the beginner, throws new light upon its phases for the expert, and, by its merely dramatic effect, emphasises the lesson for all. Again, outside considerations need not affect the sequence of a film, whose length and manner is chosen purely for its value as a teaching agent. Redundant parts can be cut out, and diagrams, explanations, or " close-ups " of essential apparatus, or part of the field of operation, may be inserted wherever further clarity is required, without the drawbacks that such acceleration or delay would involve in clinical work.

The whole question of the place of the cinematograph in medical education was reviewed by Prof. R. E. KELLY, of Liverpool, before the Surgical Section of the Royal Society of Medicine on April 6th. His lecture was illustrated by a series of films, which were all the more valuable in that they were taken by amateurs with a Cinekodak, and therefore showed what uses the teacher might make of the machine in his own work. The ground covered included operations upon the brain and spinal cord, upon an aneurysm of the carotid artery, and upon the breast with the diathermic cutting current, as well as records of the clinical features of the aneurysm before operation and the gait and facial movements of the cerebral tumour cases afterwards, and a demonstration of surgical emphysema involving the whole trunk. As Prof. KELLY explained, a film of an operation is not so much a record as an epitome, a series of excerpts showing the essential steps; but the skill with which his condensations had been made, and the high quality of his photography, should stimulate those of his hearers, whose efforts in the same field had proved disappointing, to try again. The majority of amateur surgical films are spoiled by poor focus. The method employed in Liverpool to obviate this fault—a measured piece of sterile silk fastened at one end to the wound and the other to the camera, which could then be moved to any angle at a fixed focus—is worthy of wider publicity.

The discussion which followed Prof. KELLY's paper was concerned almost entirely with the use of the cinematograph in recording surgical operations, and speakers foreshadowed the employment of colour photography and sound recording for this purpose. Indeed it is in the field of operative surgery that motion photography has so far been

[6] Cæsarean Section, London, 1925.

LOW-SEGMENT CÆSAREAN SECTION.

SINCE WILLIAM SMELLIE, two centuries ago, wrote of the Cæsarean operation it "hath been performed both in this and the last century, and sometimes with such success that the mother has recovered and the child survives," we have advanced a long way. And yet a maternal mortality of almost 2 per cent. in so-called clean cases, which is the present experience of the country as a whole, can be viewed with little satisfaction. Its meaning will be better realised when we call to mind that the general maternal mortality-rate in England and Wales is about 4 per 1000. If every woman were delivered by classical Cæsarean section before the onset of labour or early in labour the death-rate would be 20 per 1000; Cæsarean section is, in fact, five times as dangerous for the mother as delivery by the natural passages. After labour has been in progress for a considerable time and sepsis has been introduced by internal examinations and repeated attempts at delivery the results of classical Cæsarean section are of course much more serious, and may in some cases be disastrous—a mortality of 25 per cent. or more being not infrequent. It was in the hope of remedying this state of matters that in 1907 the low-segment operation was introduced, in which the child is extracted through an incision in the cervix and lower segment of the uterus. The advantages claimed are briefly these. The spill of liquor amnii is limited to the pelvis so that there is less danger of general peritonitis if the fluid is infected; healing of the wound in the uterus is better, as the lower segment is at rest in the puerperium; he uterine wound is covered by the flap of peritoneum and seepage of lochia through the wound is thus prevented. For the same reasons the operation is held to be safer in infected cases. There is said to be less liability to post-operative adhesions as the uterine scar is situated low down in the utero-vesical pouch; shock is less and the convalescence is less disturbed as the intestines and omentum do not come into view during the operation. Finally, it is stated that rupture of the scar is less common in subsequent pregnancies and labours. On the other hand there can be no doubt that the operation is more difficult and may, unlike the classical, call for a considerable experience of abdominal surgery, while a longer time is required for extraction of the child. This increased difficulty is itself regarded by some as an advantage. There is probably no abdominal operation that is more frequently tackled by amateur surgeons than the classical Cæsarean, and there is reason to believe that this largely accounts for the high mortality.

The low-segment operation, with its various modifications, has gained steadily if slowly in favour, and sufficiently large series of cases have now been reported to justify an attempt to compare its results with those of the older operation. J. P. GREENHILL (Chicago) recently reported[1] 140 consecutive cases in which the low-segment operation was employed, with no maternal deaths an a fœtal mortality of 5 (3·6 per cent.). In thre of these cases, the fœtus was dead before th operation was begun. The series included tw eclamptics, seven cases of placenta prævia, and five of abruptio placentæ, while in 14 per cent the membranes had been ruptured for 24 hours or more. He has also compiled statistics of 895 low-segment operations done by all operators including himself at the Chicago Lying-in Hospital, with a maternal mortality of 1·23 per cent. J. ST. G WILSON (Liverpool) has related[2] a series of 50 cases with no maternal death and one stillbirth V. COCQ compares[3] his results in 300 classical Cæsarean sections with those obtained in 50 low-segment operations. Of the former all but one were carried out on clean cases (dans les cas purs, he writes), the maternal death-rate being 2·3 per cent. Amongst the 50 low-segment operations there were 2 deaths (4 per cent.), but some of the patients had been in labour a long time, in some the membranes had been ruptured more than 24 hours, some had had several vaginal examinations before admission to hospital, and some had high temperatures before operation. Of the two fatal cases, one was exsanguine from unavoidable hæmorrhage before operation was begun; the other had acute pulmonary complications before operation and died of these some time afterwards. COCQ considers the low operation a much more formidable proceeding, and he deals in some detail with the difficulties encountered. In one case he found it necessary to do hysterectomy on account of downward tearing of the uterine incision. He concludes that the low operation is good in certain dystocias, but he adds a warning against undue enthusiasm. He would not, for example, substitute section for podalic version in every case of dystocia from contracted pelvis; it is, he thinks, still necessary to teach students, who may have to practise in the country, how to deliver by version in such cases. In clean cases he regards the classical as the better operation; it is simpler, and accidents in the course of the operation are rare. While after the low operation there may be less general infection there is more local sepsis in the pelvis and abdominal wall. When, however, infection is present he thinks the low operation is safer; its introduction has extended the indications for Cæsarean section. V. B. GREEN-ARMYTAGE speaks well[4] of the low-segment operation, which he has performed in 75 cases with 11 deaths (14·6 per cent.) and a fœtal mortality of 13·3 per cent.; 48 of his cases were "essentially septic" at the time of operation. "Before the war," he writes, "50 per cent. of the mothers who suffered the operation (classical Cæsarean with eventration of the uterus) after they had been hours in labour and were septic due to multiple examinations or trauma died of general peritonitis." Mrs. F. IVENS-KNOWLES has reported[5] 352 consecutive ven slowly, after the bowel has been emptied, to event the initiation of defæcation reflexes, the id-level of the reservoir from which the irrigation given being not more than two feet above the ctum. While the giving of an irrigation which iall "consume from 6 to 10 gallons and take early an hour" may seem to some a counsel of erfection for routine procedure in the hustle of odern hospital life, there will be little doubt hat a more satisfactory lavage of bowel and emoval of tenacious mucus will be obtained by his method than by the more hurried injection nder greater pressure so frequently employed.

BASTEDO has a word of warning with regard to the over-zealous self-irrigator found so frequently among patients suffering from mucous colitis, and deprecates the exploitation of the procedure by nurses and others. Amongst the commoner mishaps he mentions bleeding from the rectum, the tearing of a rectal valve, and the injury or severance of a polypus. Properly employed, however, he considers that irrigation tends to improve rather than lessen the tone of the bowel wall and serves as a valuable therapeutic measure in washing out putrefactive material and loosening mucus above the defæcation area.

ANNOTATIONS

ATEBRIN IN MALARIA.

OF late years a new interest in malariotherapy has centred round the synthetic compounds produced by the I.G. Farbenindustrie in Elberfeld; for, as was predicted, plasmoquine has proved to be the prototype of other synthetic remedies. The latest of these, Atebrin, was first mentioned in THE LANCET by our Calcutta correspondent last week, and is the subject of a paper by Dr. Richard Green in our present issue. In the *Deutsche medizinische Wochenschrift* of April 1st, which contains a whole series of reports on this drug, Prof. Walter Kikuth gives the first account of its chemotherapeutic action. Formerly called erion, it is a yellow powder which melts at 245–255° C., and is soluble to the extent of 7 per cent. at 40° C. in neutral solution. From the chemical standpoint an alkylamino-acridin derivative, it was first synthesised by Mietsch and Mauss, and when tried in avian malaria (*Plasmodium præcox*), on the lines formerly employed by Roehl in his plasmoquine experiments, it was found to be less poisonous, but also less efficient in absolute figures. Atebrin showed itself 15 times weaker in the therapeutic sense than plasmoquine, and four times more powerful than quinine. In avian malaria it did not bring about any rapid sterilisation of the blood, as does plasmoquine, but behaved in this respect more like quinine; nor were more favourable results obtainable with such other strains of avian plasmodium as *P. elongatum* and *P. circumflexum*, forms which more closely resemble the subtertian parasite in man. By ingenious experiment on the hæmoproteus infection (*Hæmoproteus orizivoræ*) of the Java sparrow, Kikuth conclusively proved that the gametocytes which appear in the peripheral blood of this bird are eradicated by plasmoquine, whilst the schizont stages which develop in the endothelial cells of the lungs are attacked by atebrin, so that in individuals treated by this combined method relapses of hæmoproteus infection can no longer take place.

Prof. Franz Sioli writes upon atebrin in therapeutic malaria in general paralysis. His results are apparently very favourable, and entirely substantiate what has been learned from experimental avian infections. Atebrin can safely be given by oral administration in daily doses of 0·3 g. (3×0·1 g.) for a period of three days (total dosage 0·9 g.). Given in this manner it appears to cause the safe and permanent cure of experimental therapeutic malaria, being at least four times more reliable than plasmoquine. Apparently after three daily doses the patient remains parasite-free for at least 34 days. Under systematic and careful observation the intracorpuscular parasites begin to show marked morphological changes after 0·3 g., and after 0·6 g. they disappear entirely. Certain toxic effects are on record; thus 0·3 g. sometimes provokes intestinal pains, and in the great majority of cases the skin assumes a yellow tint. At first this was attributed to icterus, but the coloration has now been proved to be due to the natural pigmentation of the drug. Daily analysis of the urine showed no marked excretion of urobilin or bilirubin as the result of absorption of atebrin, and this suggests that it has no toxic effect on the liver. F. M. Peter, who has used the drug in Gurbanesti (Rumania) in cases of natural infection by malaria, is able to show that in this compound we have a schizont-destroying agent of the first order. The material consisted of three cases of benign tertian malaria, the total dose of atebrin being 1·0 g. The effect on the temperature curve, as well as upon the parasites, was striking. The smaller ring forms (or schizonts) were first attacked, and the gametocytes later, while the shrinkage of the spleen was rapid and complete. In two cases of natural subtertian infection somewhat similar results were obtained; the schizonts disappeared after 24 hours, but no effect upon the gametocytes (crescents) was ascertainable. P. Mühlens has had the advantage of much more clinical material in the Hospital for Tropical Diseases in Hamburg. From his report[1] it appears that from Nov. 24th, 1930, to the end of February, 1932, 122 cases (17 tertian, 8 quartan, 85 subtertian, 2 cases of quinine idiosyncrasy, and 10 of malarial complications) have been treated alone with atebrin, or with atebrin combined with plasmoquine. The results were similar to those already related. In subtertian infections the effects upon the schizonts were far more remarkable than those of quinine or plasmoquine. Using a combination of atebrin (0·3 g. daily) with plasmoquine (0·03 g.) the gametocytes disappeared in three to six days. Mühlens further satisfied himself that the action upon quartan malaria was equally satisfactory. He has been able to employ a total dosage of 4·8 g. without producing any toxic symptoms, and considers the yellow colour of the skin to be due to acridin-staining which sometimes persists for two to three weeks. In his opinion, atebrin is equally satisfactory in all three forms of malaria, but in combination with plasmoquine it attains its maximum efficiency in subtertian infections. However, in heavy ring infections he thinks that for the first two days intramuscular quinine should always be exhibited, to be reinforced later by atebrin and plasmoquine. It is good to chiefly exploited. For the expert and advanced student such films serve a definite purpose, for they allow the demonstration to a large audience of steps that can only be seen at operation by the surgeon and his assistants, and enable a lecturer to explain the details of a new operation and the use of some special instrument in the precincts of a medical society. But it is open to question whether a film of an actual operation, even when it is carried out by a leading exponent, is of any real value in the teaching of students. The absence of colour and contrast, the high lights that are reflected from moist tissues, the ooze of blood and movements of swabbing, and the multitude of unessential instruments that crowd the field on the screen, all lead to a confusion that can only be sorted out by the practised observer. A film of an operation is essentially an adjunct to a lecture by the operator himself, and the circulation of library films is very prone to degenerate from teaching to propaganda. The purely teaching film, designed and photographed for the instruction of beginners in the elements of operative surgery, is yet to be made, but a pointer of the way in which such a film should be arranged to be of the greatest value is provided by that dealing with infections of the hand, which is included in the Kodak library. Such a film might commence with a short history of the operation, and an account of the indications for its performance with diagrams of the main steps in the technique. The actual operation should be carried out on the cadaver, where the distance of the camera is dictated only by the size of the field to be shown and not by the needs of asepsis, for thus attention is not distracted and vision hampered by retractors, hæmostats, and the hands of assistants, while the tissues are not stained by blood, each step can be carried out deliberately, and the anatomical landmarks of the region can be pointed out as they are exposed. Each step should be explained by captions, and the special instruments that are required should be shown in "close-ups" before they are brought into use.

---

[1] Münch. med. Woch., April 1st, p. 537.

The cinematograph will surely find its place in all branches of the curriculum, and in the earlier years should fill an even more useful part than that which it has till now occupied in the later stages. It is hardly necessary to point out that the difficulty, insuperable in this country, of repeating before students more than a small number of the animal experiments upon which physiological knowledge is based, could thus be overcome; and that in anatomy films could be used to demonstrate, as no other method can, those structures which can only be shown in specially prepared subjects under exceptional circumstances. But the use of a cinematograph is not limited to photography. The animated cartoon, immortalised by "Felix" and "Micky Mouse," would delineate, with a lucidity that could not fail to carry conviction, the processes of intestinal rotation and all those intricate facts of embryology which even the pen of a Keith has not been able to describe in words that the beginner can master without intent and repeated application.

THE USES AND ABUSES OF THE COLON.

For many years the colon has been a centre of interest to laymen and the medical profession alike. It has been douched, bathed, stimulated, soothed, anæsthetised, fed, and more recently psychoanalysed with an enthusiasm which, perhaps, no other single organ of the body can lay claim to have aroused. But in many quarters a note of warning and a plea for a more rational approach is now being sounded. Not only is the more elaborate nutrient enema now a thing of the past, but doubt has even been cast on the efficacy of the glucose enema as a means of administering carbohydrate. We have little positive evidence as to the actual amount of glucose which can be absorbed by this route, since neither the blood-sugar curves, nor changes in the respiratory quotient, nor even analyses of the subsequent fæcal return provide at all an accurate means of quantitative estimation. A recent study by Dr. F. L. Scott and Dr. J. F. B. Zweighaft,[1] carried out on medical students, showed a slight fall in the blood-sugar during the three hours succeeding the administration of 200 c.cm. of 10 per cent. dextrose solution per rectum, and this they suggest may possibly have been due to stimulation of pancreatic activity by the absorption of a small amount of dextrose, or more probably to chance variation; they also found that a variable and frequently considerable proportion of the dextrose administered may be recovered from the stools after two and one and a half hours.

Attention has also been drawn to the dangers both of unskilful administration and indiscriminate use of enemata and colonic lavage. Dr. H. H. Rayner [2] has lately described the severe trauma and extensive sloughing that may result from the use of an unguarded bone or glass nozzle of an enema syringe—penetration of the anal mucosa being followed by fluid forced under pressure into the submucosa, while reference has been made in our columns (The Lancet, 1931, i., 600) to the warning of J. Friedenwald and M. Feldman[3] as to the inflammatory changes which may follow the repeated use of irritating chemicals, including sodium carbonate and even soap-sud enemata. A detailed summary of the technique, therapeutic applications, and dangers of colonic irrigations, written by Dr. W. H. Bastedo for the American Council of Physical Therapy, appears, therefore, at an opportune moment.[4] While he distinguishes irrigations from enemata as having primarily the function of lavage whereas the latter are intended to produce defæcation, many of his observations are equally applicable to both. He considers the insertion of stiff tubing for more than 5 or 6 inches into the rectum not only useless, owing to the fact that greater lengths tend to curl up in the rectal ampulla, but dangerous. In colonic irrigation he recommends the use of an inlet and an outlet tube, and plain water at or just above body temperature; the irrigation should be nd a flow of secretion containing hydrochloric acid nd pepsin, changes which could be prevented by previous section of the vagi. When the vagus was divided and its central end anastomosed with the peripheral end of the cut phrenic (a sufficient interval being allowed for regeneration), hypothalamic stimulaion caused contraction of the diaphragm. Another significant observation was that prolonged stimulation ed to the appearance of small areas of hyperæmic mucosa near the lesser curvature of the stomach. Beattie's preliminary results therefore not only afford evidence of the situation of the parasympathetic centre, but also promise to throw some light on the ætiology of gastric ulceration.

THE MEGALOCYTIC ANÆMIAS.

THE old classification of anæmias as primary or secondary has rapidly given way in the last few years to one dependent upon the size of the red cells. C. Price-Jones has recently elaborated his earlier work on red cell size and has determined by refined statistical methods both the smallest and largest possible normal red cell distribution curves. A condition, therefore, in which the red cells show on measurement a curve falling to the right of the largest possible normal can be described as a megalocytic anæmia and one where the curve falls to the left of the smallest calculated normal, as a microcytic anæmia. Certain cases within normal limits have been described by M. M. Wintrobe as normocytic. This variation in size of the red cells appears to have a direct relationship to the ætiology of the anæmia. Thus the microcytic anæmias respond to massive iron dosage, while the majority of the megalocytic anæmias can be relieved by adequate administration of liver extract or its substitutes. The problem of the megalocytic anæmias is becoming increasingly complex however, as was shown in the discussion at the Royal Society of Medicine reported on p. 836. Castle's fundamental observations on the ætiological significance of a failure of gastric secretion in Addisonian anæmia forms the basis for his hypothesis that a similar failure is the cause of all megalocytic anæmias, associated in some instances with faulty absorption. This is supported by the finding that the majority of such anæmias are associated with a demonstrable gastric lesion: sprue, idiopathic steatorrhœa (which probably includes the majority of conditions described as fatty diarrhœa, cœliac disease, chylous diarrhœa and pancreatogenous diarrhœa), gastro-colic fistula, intestinal anastomoses and resection, gastrectomy, carcinoma of the stomach, and bothriocephalus anæmia. The group are all relieved by the suitable administration of the effective principle in liver. It is possible that the tropical anæmia described by Dr. Lucy Wills in which there is no demonstrable gastric deficiency is dependent upon lack, not as in the others of Castle's intrinsic factor, secreted in the gastric juice, but of his extrinsic factor supplied in the food, since all Indian diets are notably deficient. Such a case of typical Addisonian pernicious anæmia occurring in a strict vegetarian with apparently normal gastric secretion and relieved by diet alone has been described.[1] Dr. Goodhart discussed, however, an extremely interesting group of cases associated with a variety of conditions as pulmonary tuberculosis and Hodgkin's disease which failed to react to liver or liver extract given by mouth and which in some cases showed no obvious intestinal lesion. They had certain features in common which distinguished them from Addisonian pernicious anæmia. The Price-Jones curve appeared on inspection to be relatively symmetrical and though, as Dr. Price-Jones remarked, this does not mean that it was so mathematically, it was an appearance common to the group and therefore perhaps significant. Many of them, in spite of a leucopenia, showed a shift of the Arneth count to the left which is never seen in the idiopathic form and in none were the characteristic multilobed polymorphs found. Dr. Vaughan and Dr. Hunter also point out in their observations on idiopathic steatorrhœa published in our present issue that Addisonian pernicious anæmia can be clearly differentiated from a further large group of megalocytic anæmias possessing certain features in common. Sprue, tropical anæmia, megalocytic anæmia associated with gastro-colic fistula, and idiopathic steatorrhœa have a low indirect van den Bergh reaction, as did many of Dr. Goodhart's cases, suggesting that there is less disturbance of pigment metabolism than in the idiopathic type. Poikilocytosis is not a marked feature of the stained films and hydrochloric acid is frequently present in the gastric juice or returns after treatment. The anæmia of sprue, tropical anæmia, and idiopathic steatorrhœa responds as dramatically to marmite as to liver extract while Addisonian anæmia is unaffected by marmite. Marmite is a complex substance and it is not yet clear how far its action is associated with its vitamin B content. It is important that in the future all megalocytic anæmias, other than the idiopathic type, should receive adequate treatment with marmite, which is relatively inexpensive, in order to determine how far a response to the effective principle in liver is peculiar to Addisonian pernicious anæmia. Information on this point should help towards a reasonable classification and understanding of the pathology of megalocytic anæmias.

DESENSITISATION OF RHEUMATIC CHILDREN.

MANY supporters have been found for the theory that the clinical manifestations of "rheumatic fever" represent the allergic response of a subject sensitised, by previous infection, to certain strains of hæmolytic streptococci. Though by no means proven, this theory explains the facts better than any other yet put forward, and may be regarded as a base from which to attack this condition, which has hitherto been approached along purely empirical lines. It is during the recurrences that the worst damage is done, and it was first pointed out by Swift and his collaborators[1] at the hospital of the Rockefeller Institute that, granted the allergic view of the condition to be correct, the rational thing to do would be to try to desensitise the subject after the first attack, in the hope of thereby reducing the incidence and severity of later illness. The possibilities of this procedure have lately been explored by Wilson and Swift,[2] working in the Cornell University Medical School, and the results have been encouraging. They took a group of about 180 children who had suffered from rheumatic fever, and divided them into a test and a control group. The children of the test group received intravenous injections of a vaccine made up from hæmolytic streptococci isolated from a rheumatic subject; the note that atebrin is well borne in cases of quinine idiosyncrasy and in the pre-blackwater state. In Mühlens's opinion the atebrin treatment of malaria is in its ultimate results at least equal to those obtained with chinoplasmin and plasmoquine compound.

[2] Wilson, May G., and Swift, Homer F.: Studies from the Rockefeller Inst. Med. Res., Reprints, 80, 1932 (from Amer. Jour. Dis. Child., 1931, xlii., 42).

We therefore welcome this the latest addition to malarial therapeutics. The early promise of this branch of chemotherapy has already borne good fruit, and we have now been given two new and powerful remedies. But in order to estimate the exact value of atebrin in the campaign against malaria a vast amount of work will have to be done.

GRADE A HEALTH FACTS.

In a recent lecture delivered at the Royal Institute of Public Health[1] Prof. H. R. Kenwood remarked on the economy of effort and money which would result if all health propaganda could be made sound and therefore harmonious. Uniform health advice would, he said, have great weight with the public. The same thought is moving in America, as seen in the sound and vigorous attitude towards health education taken[2] by Dr. Donald B. Armstrong, a high official in one of the largest American life assurance companies. Dr. Armstrong disagrees emphatically with what he calls the "extreme individualism and pessimism" shown by Dr. Robert Hutchison at the Winnipeg meeting last summer. He is certain that health must be taught to the public, and he agrees substantially with the manner of teaching set out in a leading article[3] on Dr. Hutchison's address. Dr. Armstrong demands the presentation of health rather than disease, and of health as a basis for growth, character, and happiness. He classifies facts into three grades: scientifically certified facts; items that are probable but are not quite certain, including certainties of a previous generation which are now becoming questioned and possibilities that increasing experience is making more probable; and items extensively used as facts, especially for commercial exploitation, which are either erroneous or designedly misleading. He classes the work of Dr. Sherman and others on the vitamins as Grade A facts suitable for public examination, and he feels on fairly sure ground when teaching the value of sunlight and the dangers of communicable disease. Nevertheless, he admits difficulties in method. While to a certain extent he approves as a sound objective the slogan "Find Disease Early," he points out that the periodic health examination, though good in theory, is a very frail instrument in practice. The public is not yet educated, he says, to go to the doctor early enough; the doctor is not sufficiently interested nor able to carry out all the necessary tests, and few communities can direct the public to proper sources of such service. He holds, however, that the public should be taught not to be afraid of fact, and that health suggestion comes better from the physician on a basis of fact than through quackery and patent medicine advertisements. One of the chief needs of the community is, he thinks, a mechanism for individual guidance, and this, he suggests, could best be given by the private physician under the auspices of county medical societies. He warns medical publicists to be more cautious in their popularised forecasts. The slogans "No Tuberculosis by 1915" and "No Diphtheria by 1930" aroused great interest and effort and the fact that they were not realised caused little disappointment, but he thinks it inadvisable to prod the frail public memory too frequently with explosive health campaigns, the promise of which can hardly ever be fulfilled. While granting the necessity to be assertive and dogmatic, he adds, "There is some admitted hokum in our health educational program, and the public is in a debunking mood. Let us therefore keep, so far as possible, within the realm of the attainable." Yet he tolerates health rules such as those advising the consumption of a certain number of glasses of water a day or the enjoyment of an average of eight hours' sleep every night, the value of exercise in promoting longevity, and the necessity for brushing the teeth twice a day—justifying them by the need for being direct, simple, and dogmatic.

In the same issue of the *American Journal of Public Health*, Mr. George F. Wright, Editor of the *Montreal Star*, tells us what constitutes health news from the point of view of the lay press. He points to a fault, to which some of us may have to plead guilty—viz., a rooted objection to the presentation of medical research and discovery in an attractive form. Nobody, he says, would read an account of a discovery presented in a methodical and orderly fashion, for it would be immeasurably dull. Nevertheless, he asserts that a strict adherence to fact is the one motto which an editor is always placing before his staff. He believes that the cause of public health is best advanced by the newspaper reader getting into his brain the necessity of carrying out certain simple rules of living. For this the constant reiteration of plain truth is of some value, but the artful presentation of that truth in many varying forms counts for much more.

A PARASYMPATHETIC CENTRE IN THE HYPOTHALAMUS.

The influence exerted on metabolism and visceral activity by the two opposing divisions of the autonomic nervous system—the sympathetic and parasympathetic mechanisms—has long been recognised. The precise situation of the centres controlling these mechanisms, however, is only just coming to light. A considerable amount of indirect evidence has pointed to the hypothalamic grey matter in the floor of the third ventricle as the seat of the sympathetic nucleus, and direct proof has recently been forthcoming, in the demonstration by J. Beattie, G. R. Brow, and C. N. H. Long,[1] of Montreal, of a tract of fibres linking up this region of the brain with the lateral horns of the grey matter of the spinal cord. About the position of the parasympathetic centre there remains some doubt. Harvey Cushing[2] believes it to be situated, like the sympathetic nucleus, in the hypothalamus, and has shown that injection of pituitrin into the ventricles of the brain of human subjects leads to increased salivation and to increased mobility and hypersecretion of the stomach. J. Beattie[3] has just reported, in outline, some experiments on animals which support Cushing's suggestion. Beattie stimulated the anterior portion of the hypothalamus electrically and studied the effect on the stomach, in some instances by direct examination of the exposed organ, in others by suturing electrodes into the stomach wall and obtaining graphic records on electrocardiographic plates. He found that hypothalamic stimulation causes increased peristalsis

PANEL AND CONTRACT PRACTICE

Distribution of the Central Pool.

THE central pool, it may be recalled, is the sum of money represented by the number of insured persons in the country multiplied by the capitation fee. The number of insured persons must in the nature of things be always varying owing to deaths, new entrants into insurance, members becoming dis-entitled to benefit, and so forth. The figure has therefore to be arrived at by actuarial calculation by the Government Actuary. The method employed has been tested on behalf of the profession by an independent actuary and has been proved to be a sound method of calculation. As a further safeguard it has been usual for the Distribution Committee (on which are representatives of the Government Actuary, of the Ministry of Health, of the Insurance Acts Committee, and of rural practitioners) to meet annually to advise the Minister of Health as to the method of distributing the central pool amongst the various insurance committees.

The Distribution Committee did not meet formally this year, but figures have been compiled at the Ministry of Health from returns given by insurance committees and others show that for 1931 the calculation of mileage grants to rural areas have been based on recently obtained figures of claims instead of as last year on those for 1927. Scrutiny of these figures shows that 14 counties (Bedfordshire, Cornwall, Durham, Essex, Herts, Isle of Ely, Kent, Lancs, Rutland, Sussex East, Sussex West, Worcestershire, Yorks North, Westmorland) have on each occasion increased their mileage claims, whilst 11 counties (Bucks, Cambs, Isle of Wight, Lincoln Lindsey, Oxford, Wilts, Hereford, Leicestershire, Notts, Salop, Bury) have on each occasion lost a proportion of that grant. Figures of other committees have not altered much one way or the other. In 1930 the Distribution Committee advised that units should be calculated from the doctor of choice and not from the nearest available doctor. Insurance committee returns had previously varied on this point.

1 unit is	obtained for each insured *person living over*	2 miles and under 3	from his doctor.
2 units are		3 " " " 4	
3 " "		4 " " " 5	

The total mileage grant is £250,000, divided proportionately amongst the insurance committees according to the number of units claimed. There is an additional allowance for specially difficult places.

The apportionment of the central practitioners' fund for the year is arrived at by adjusting the index register apportionment of each insurance committee. The figures supplied by the Ministry are expressed as a percentage of the whole insured population—e.g., London has 12·9748 per cent. of the insured population, and therefore of the fund. The first adjustment of this is for temporary residents. Some committees, e.g., those in seaside resorts, have a percentage addition. Others, e.g., London, have a deduction made for temporary residents, more of whom they send away to other committees than they receive from them. The deduction for London for 1931 was 0·0714 per cent. Deductions are also made for institutions recognised under the Insurance Acts, for mercantile marines, and for persons who are allowed to make their own arrangements. London has no institution deduction, but it loses 0·0356 per cent. for mercantile marines, and 0·0091 per cent. for "own arrangers." In this way a net figure is arrived at for each committee, the London net figure becoming 12·8587 per cent. These net figures added together do not make 100; a final adjustment is therefore made so that they do become percentage figures, and this adjustment makes London's final figure 13·0425 per cent.

These figures illustrate how the character of insurance practice varies in different localities, and how insurance committees vary in their decisions upon "own arrangers." The Ministry of Health also supplies the Distribution Committee with the quarterly count during the year of each insurance committee index register. These figures show the movements of the insured population from one area to another, and where the population is going out of insurance. In the county boroughs the tendency is as follows:—

Count going up—plus.	Count going down—minus.	
Brighton.	Barrow.	Bradford.
Blackpool.	Birkenhead.	Burnley.
Hastings.	Bristol.	Halifax.
Southend-on-Sea.	Newcastle.	Huddersfield.
Southport.	East Ham.	Middlesboro.
Birmingham.	West Ham.	Oldham.
Manchester.	West Hartlepool.	Nottingham.
Croydon.	Bolton.	Preston.
Oxford.	Bootle.	
Worcester.		
Exeter.		
Portsmouth.		

The last set of figures supplied to the Distribution Committee shows the amount paid per name on doctors' lists for each committee. The figures this year relate to 1930, and so do not take into account the 10 per cent. deduction. Committees with a payment of less than 9s. evidently have more names on their index than should be there: presumably duplication is going on and the necessity arises for the "clearance" of the register. The same thing may be caused by the allocation to doctors in the area of all names who have not chosen a doctor; this, however, is not a common practice amongst insurance committees. Those committees whose payment per capita is over 9s. are frequently those whose locality makes them likely to receive many temporary residents. The figure for London is 9s 1d.; for Blackpool, 10s. 2d.

The total number of insured persons for last year on the central register was 14,896,630, being the mean of four quarters' counts. The total fund available for the central pool would have been £6,638,051, but with 10 per cent. deduction in respect of the four quarters the amount available for the year was £6,467,625. With 10 per cent. deduction for the whole year the fund is estimated at £5,800,000.

References to Regional Medical Officers.

"Both personal experience and an accumulating mass of correspondence in the medical press," writes Rural Panel, "bear witness to a widespread and growing discontent with the present system by which the selection of patients to be referred to the regional medical officer is governed. When the panel practitioner finds that he is requested to provide information about patients who have left the district weeks before, who are moribund, who are 'referred' after three days of an illness such as 'acute tonsillitis,' or who have been 'referred' so repeatedly that they 'sign off' in disgust though incapable of resuming work, he not unnaturally blames the person who is ostensibly responsible for the selection—i.e., the regional medical officer.

injections were given intravenously, beginning with a dose of 250,000 and working up to 10,000,000; the inoculation was done during two successive years: in the first throughout the late summer, autumn, winter, and early spring; and in the second in winter and early spring only. A comparison of the case-histories of the two groups shows a significant diminution both in the incidence and severity of rheumatic manifestations in the treated group. The investigation is of interest from several standpoints. Apart from its value as an indication of a method of attack upon one of the most disabling of all diseases, it draws attention afresh to the allergic factor, consideration of which has been almost swamped of late by concentration upon "infection." Further, it emphasises a side of vaccine therapy which has been comparatively neglected. Asked what they expect to do with a vaccine, most medical men would probably assert that they hope to "immunise" the patient. Certainly the possible uses of desensitisation are too often overlooked.

HOUSING IN KENSINGTON.

FEW boroughs have such an abrupt division of amenities as Kensington, where the southern half is a superior residential quarter and the northern an area of overcrowded tenements. The recent survey of housing in Kensington made by Irene T. Barclay and Evelyn E. Perry quotes repeated examples of the following kind:

"Two basement rooms, the back one damp and dark. The family here is a husband and wife, a boy of 13 and girls of 11, 10, 8, 5, 3, and 1—nine persons. The tenant has regular work and an average wage of £3 5s. per week. He wants open air and a garden and is anxious to go to an outlying L.C.C. estate if he can have a cottage at a rent within his means. . ."

In a foreword to the survey by Mrs. Victoria de Bunsen and Major-General Neill Malcolm the problem is described as overcrowding aggravated by bad basements. At the 1921 Census the Registrar-General found that the number of persons living at a room-density of more than two per room was no less than 26,456, and the surveyors conclude that the whole building, carried out by combined public and private activity since the war, has only served to pr[illegible] from becoming worse. Legal [illegible] on air space per person, is not the rule, but the inadequacy of the standard adopted can be appreciated from the fact that it is possible for a parent and eight children to live in two rooms of an ordinary Kensington house without being legally overcrowded; but on the Registrar-General's standard overcrowding is present in 76 per cent. of cases. It is, apparently, seldom possible for a husband and wife to occupy the same bedroom without involving the family in a breach of the by-laws relating to separation of the sexes; and a living room not used also as a bedroom is a rarity. The chief obstacles to any building programme sufficiently large to relieve the situation are, of course, the scarcity of sites and lack of funds. The financial requirements could be covered by quite a small addition to the rates; a building scheme recently approved by the borough council would mean an addition of only twopence a year to a house rated at £100. The scarcity of available sites does not seem to be insuperable, and the surveyors think it would be possible to effect a very great improvement within a few years. Many of the existing buildings in a street named in the report are insanitary and verminous and have been condemned. The report of the school doctor shows that children coming from this street are subnormal in health, and compare unfavourably with those from other streets, but while there is no alternative accommodation for the 58 families inhabiting the street it cannot be pulled down. In the words of Dr. Leonard Huxley, writing recently in the Cornhill Magazine, "why not avert the blow instead of healing the wound? We tend the sickly but do not create the healthy—we punish wrongdoers but see the good seed swamped in the morass—we educate, but there is no chance of knowledge spreading in such hopeless surroundings."

The Kensington Housing Association is holding an open meeting at the Kensington Town Hall on Monday, April 18th, at 8.15 P.M., at which Dr. Raymond Unwin will speak on the town planning of Kensington.

COMPULSORY STUDY OF THE HISTORY OF MEDICINE.

Prof. W. Szumowski of Cracovia, Poland, recently read a paper at the Eighth International Congress of the History of Medicine advocating the compulsory teaching of the history of medicine in the universities of the world. Such teaching, he thinks, should be given to the medical student during the first year of his training and should be rendered effective by an examination. The suggestion, no doubt, is good in theory but is impracticable in practice, at any rate in Great Britain. The difficulties of educational authorities in dealing with the medical curriculum are acute, and the introduction of another compulsory subject would not be contemplated by any university or corporation. A few students having a bent towards the historic or antiquarian side of their studies will always show an interest in the history of medicine, but its teaching should be post-graduate and its study left to a more mature age, when leisure, curiosity, and a cultivated taste have developed an appetite for literary knowledge; and by this time formal instruction becomes unnecessary, while compulsory study has never produced satisfactory results in England when voluntary efforts have often been fruitful. The Section of History of the Royal Society of Medicine provides a meeting-place where historical comment and the outcome of historical research can be ventilated, while students' clubs, formed in connexion with their own hospitals or elsewhere, give opportunity for similar discussions among the younger generation.

Summer Time will commence in Great Britain, Ireland, the Channel Islands, and the Isle of Man on Sunday morning next, April 17th, at 2 A.M., when the hands of timepieces should be advanced one hour. It will end on Sunday, Oct. 2nd.

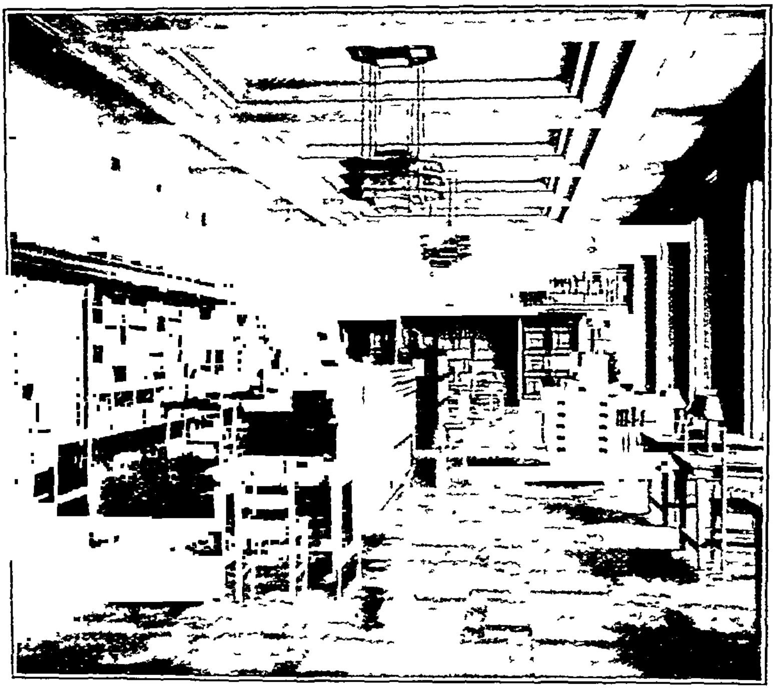
SCARCITY OF HOSPITAL MAIDS.—The matron of the Enfield and Edmonton Joint Hospital reports a difficulty in obtaining maids, most of whom are quickly incapacitated by illness, the result of the "desperately hard" work. Lack of accommodation makes it impossible to employ a larger number of girls. The difficulty is to be met by employing married women when needed—single women will not apply for daily work—and by giving three weeks' annual holiday instead of a fortnight. It was stated that other hospitals are experiencing a similar difficulty.

SPECIAL ARTICLES

THE LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

THE Court of Governors of the London School of Hygiene and Tropical Medicine has elected Sir Austen Chamberlain as chairman of the Governors and after the ceremony, which took place on Thursday, April 7th, Sir Austen presided at a luncheon given in the library of the School.

Sir Hilton Young proposed the health of Sir Austen, and pointed out his peculiar fitness to fill the post, and meet the responsibilities thus assumed. His appointment, said Sir Hilton, was the outward and visible sign of the association of his family with the development of tropical medicine. He recalled the original work of their chairman's father, Joseph Chamberlain, and the activities of his brother, Mr. Neville Chamberlain, who, when Minister of Health, laid the foundation-stone of the premises in which they were sitting. Speaking himself as Minister of Health, Sir Hilton said that the fundamental benefits which the Empire could bestow upon its dependencies were two, peace and health. The provision of medical and hygienic services in the colonies promoted these two objects, but the services could only be carried on by the setting up and maintenance of active scientific research.



Library of the London School of Hygiene.

Sir Austen, in replying, was reminded that 40 years ago his father, at the inaugural meeting of the School, had pointed out that the greatest enemy of the Empire in its dependencies was not the survivals of barbarous customs, nor the hostility of opposing chiefs, nor the geographical and natural attributes of countries where nature had held unfettered sway; it was the incidence of disease which destroyed or weakened the personnel of those engaged in the labours of colonisation, killing many and weakening or shortening the lives of very many more. He read the following extract from the *Lagos Standard* of September, 1898:—

> "There is no doubt that something should be done to relieve the grave-diggers from the strain of the work to which they are continually subjected. The demands of a constantly increasing death-rate, which has caused the cemeteries to be enlarged, make it necessary that the number of grave-diggers should be increased. No holidays—at it from 6 A.M. to 6 P.M. every day, Sundays included, for the grim Reaper is ever busy."

"While I do not," he said, "recommend Lagos as a health resort the picture in 1898 enables us to understand the gulf which had been traversed during 40 years. The huge improvement in the death-rates of various tropical dependencies can only stimulate further work, and how vast that work is would be obvious when the long list was recollected of diseases which still infested these countries." It was true, he said, that many of the old problems were no longer insoluble, and that we could look forward to the eradication or the rendering innocuous of pestilences which once were a scourge; but in tropical disease there was urgent work yet to be done, both humanitarian and utilitarian. And as the diseases were conquered the development of trade would follow. He next referred to the need of turning attention to the problems of health at home, for it would be wrong, he said, even on this occasion, to look only at tropical medicine. On all sides there was a field of inquiry and research which grew larger with every discovery, while every discovery in one department of medical science helped not some particular area or some particular country but the world at large. He knew that the School would receive the coöperation of other countries in endeavours made for the general service of mankind. Sir Austen concluded by proposing the toast of Sir Holburt Waring, the retiring chairman of the Court who had for eight years assisted in the developments of the institution.

Sir Holburt Waring briefly replied.

A large and representative gathering of guests was present and among the telegrams of regret for inability to be present was one from Sir Henry Wellcome, sent from New York, which ran as follows: "Cordial greetings and best wishes for the continued success of the noble work founded and organised by Joseph Chamberlain and Patrick Manson. Deeply regret absence."

"It now has been made clear, however, that the choice of whom to 'refer' is not in any way under the control of the R.M.O., but rests entirely in the hands of the approved society concerned. Moreover, the practice of different societies varies enormously. In an investigation by the Reading Panel Committee it was found that 70 per cent. of the 'references' came from three industrial societies, while less than 1 per cent. were 'referred' by friendly societies. In one case a doctor wished to refer a patient to the R.M.O. with a view to getting further advice on his condition, and was told that the society in question had never 'referred' one of their members yet, and didn't intend to do so! Again, one society is alleged to refer patients without any consultation with their local officers at all. It is also alleged, incredible as it may seem, that Form R.M. 2 may be sent out by the society to the panel practitioner direct, in spite of the fact that it is addressed from and signed by the R.M.O. This is supported by the fact that the interval between the issue of the first certificate and the 'reference' is sometimes too short—e.g., two days—for it to have been through the hands of the R.M.O.

"All this does not mean, presumably, that the system has been changed, but that since the trouble about 'excessive certification' arose, and since the publication of the now notorious I.C. 329 references to the R.M.O. have increased to such an extent that the panel practitioner, instead of regarding them as a rather bad joke, feels like a babe in the wood being buried alive by showers of R.M. twos and threes. He is therefore beginning to inquire as to what particular robin is responsible for this embarrassing fate. The results of these inquiries, if correct, are certainly surprising, and throw a new light on the position and functions of the regional medical officers. These gentlemen, it appears, instead of being the principal villains of the piece recede into the status of hired bravoes, a position which they doubtless feel as acutely as anybody.

"Seriously, however, the conclusion cannot fail to be drawn that a very great deal of time and some money is being wasted, and it seems an opportune moment for an inquiry by the Ministry into the whole system."

National Formulary.

The London Panel Committee at its last meeting returned to a consideration of the directions for use printed with the formulæ in the National Formulary. A motion submitted by the pharmacy subcommittee, "that the Insurance Acts Committee be informed that the Panel Committee is of opinion that instructions to pharmacists for the administration of mixtures should be deleted from the next issue of the National Formulary," was lost. It was felt that the convenience of many panel prescribers should not give way to the difficulties of the few who have trouble with the directions.

Thermogene Wool.

The same subcommittee reported that the London Insurance Committee, under Article 4 (1) of the Medical Benefit Amended Regulations, 1930, has referred to the panel committee for consideration an appeal against its decision that the substance ordered (thermogene wool) did not form part of medical benefit; in other words, that this was an appliance and not a drug. The appeal was heard by the subcommittee, representatives of the insurance committee and of the Ministry of Health being present. The appeal was allowed on the ground that the action of the capsicum content of the wool was the chief reason for ordering this substance, and the action of capsicum was undoubtedly that of a drug. A court of referees may be set up to make the final decision.

Interpretation of "Personal Service."

The ethical subcommittee of the London Panel Committee has considered the case of the elderly practitioner and his assistant mentioned in these notes some weeks ago.[1] This case, in accordance with regulations, was referred to the panel committee by the insurance committee after the latter had passed a resolution that permission to employ an assistant should be withdrawn. The panel committee, after pointing out that there had been no complaint by any insured person and that the regulations on personal service—namely, continuity of treatment and availability of principal if asked for—had been carried out, passed the following resolution:—

> That the committee do inform the insurance committee that although it strongly objects to the principle of "farming out," after investigation it is of the opinion that the conduct of this practice does not come within that category. It considers that the insured persons concerned have not suffered in any way by reason of the manner in which the practice is being conducted.
>
> The committee recognises that whilst the principal practitioner does not take a very active part in the conduct of the practice, acting chiefly in a supervisory capacity, he is undoubtedly available for consultation and supervision, and the results of this arrangement are in no way detrimental to the interests of the insured persons concerned, the principles of continuity of treatment and availability on request having been preserved. The committee is further of opinion that it would be unreasonable to withhold permission to employ an assistant in this case, and would point out that such action would be injurious to the practice, as it would entail a fresh practitioner being brought in, the present assistant being unwilling to accept a partnership.

The matter will now presumably go to the Ministry for final decision.

---

[1] THE LANCET, Feb. 27th, p. 478.

British Empire Cancer Campaign.—In the absence of Lord Reading, Sir John Bland-Sutton presided at the quarterly meeting of the Grand Council of the British Empire Cancer Campaign held in London on April 11th. The following grants, totalling £10,000, were made in furtherance of cancer research: £500 to St. Mark's Hospital, £2500 to St. Bartholomew's Hospital, £1500 to the Cancer Hospital, and £5500 to the Middlesex Hospital. The nomination of Mr. W. Sampson Handley to act as the representative of the Queensland Cancer Trust on the Grand Council, and the election of Dr. G. Fildes, as an additional member of the Radiology Committee, which acts jointly for the Medical Research Council and the Campaign, were confirmed. The report of the judges of the 1931 Garton prize essays on the Early Diagnosis of Cancer was received. The judges reported that in their opinion none of the essays was worthy of the prize and the Council accordingly resolved that the prize for 1931 be not awarded. Dissertations for the next Garton prize, on the Biological Effects and Mode of Action of Radiations upon Malignant and other Cells, are due to be received not later than Dec. 31st, 1933. Arrangements have been made in collaboration with the Queen's Institute of District Nursing and the public health section of the College of Nursing, whereby copies of the Campaign's official publication "The Truth about Cancer" will be made available for the active members of those organisations.

Hospital Sweepstakes and Public Assistance.—In consequence of the Louth County Infirmary having received £30,000 from the Free State Hospital Sweepstakes the Louth county council has refused to continue its annual subscription of £1400. The council contends that the infirmary now has plenty of money, and is likely to receive more from the recent sweepstake on the Grand National. The infirmary's reply is that it is no better off than before, since the new invested money merely replaces the public grant. The county council's rejoinder is that for many years it has paid £700 in excess of its legal liability because of the infirmary's urgent need of money, and that it ought to be credited with the excess now that the hospital is no longer financially embarrassed. The infirmary claims that under an Act of Parliament it is entitled to a minimum sum of £320 per annum.

REFERRED PAIN IN VISCERAL DISEASE.

To the Editor of THE LANCET.

SIR,—It is plain from Mr. D. Ligat's letter in your issue of April 2nd that he uses the term "viscero-sensory reflex" in a sense very different from that given to it by Mackenzie, its originator. After asking whether a viscero-sensory reflex as described by Mackenzie exists, or whether I am right in asserting that it does not exist, he quotes a passage from my book on Abdominal Pain which he believes to involve a refutation of my own argument, and remarks at the end of his quotation, "Surely Mr. Morley here postulates a true viscero-sensory reflex?" But the passage he quotes describes the splanchnic inhibitory reflex, which has nothing in common with the mechanism conceived by Mackenzie as the viscero-sensory reflex. Mackenzie defines his viscero-sensory reflex as superficial pain and hyperalgesia referred to the somatic sensory nerves of the skin and subcutaneous tissue of the abdominal wall, resulting from violent stimulation of the afferent nerve-endings in the viscera. Viscero-sensory "radiation" would have been a better term than viscero-sensory "reflex," because Mackenzie's conception was not that of a true physiological reflex arc. But I have used Mackenzie's term because it is generally understood, and I have used it strictly in Mackenzie's sense throughout. I suggest to Mr. Ligat that in discussing the validity of Mackenzie's theory he must begin by accepting Mackenzie's definition of that theory. The extract from my book that Mr. Ligat quotes is singularly unfortunate for his argument, in that it begins, "When we explore an abdomen under a general anæsthetic . . ." An unconscious patient could hardly evince Mackenzie's viscero-sensory reflex or any other pain mechanism.

I am, Sir, yours faithfully,

Manchester, April 8th, 1932. JOHN MORLEY.

THE DURATION OF THE RED LOCHIA.

To the Editor of THE LANCET.

SIR,—I have a great admiration for the work done by Dr. Remington Hobbs in the treatment of puerperal sepsis by glycerin drainage, but I feel that his efforts to establish glycerin as the panacea of nearly all obstetric and of many gynæcological conditions is being carried too far. Already to my mind it enjoys a reputation which it does not altogether deserve.

He states that prolongation of the lochia after the seventh day is due to sepsis of the uterine mucosa, and that in cases of subsequent peritonitis a history will be found of prolonged lochia for some weeks. In my experience one can fix no day between the seventh and the twelfth when the cessation of lochia can be regarded as abnormal. The amount and duration of lochia in a normal puerperium depends on the type of labour, upon bleeding during labour, and upon the size of the infant and of the placenta. Any loss after the twelfth day should be regarded as secondary post-partum hæmorrhage, and is in the vast majority of cases due to retained products, uterine displacements, tumours, and general diseases, and should be treated as such by an exploration of the uterus under anæsthesia. It is unwise to postulate the seventh day as that on which the uterus must cease its perfectly normal and beneficent drainage, and to begin manhandling it as septic is mischievous.

Again Dr. Hobbs claims, almost with pride, that out of 340 consecutive deliveries, he detected 80 as being septic. The fact that 40 were apyrexial (simply draining their uteri as Nature intended them to do) is in my opinion no indication for treatment; it is creating a disease which does not exist, and I suppose will later supply a series of statistics illustrating the curative powers of glycerin.

I am, Sir, yours faithfully,

A. MORRIS JOHNS.

Wimpole-street, W., April 7th, 1932.

USE OF TUBERCULIN IN DIAGNOSIS.

To the Editor of THE LANCET.

SIR,—The usefulness of Dr. D'Arcy Hart's report on the Value of Tuberculin Tests should certainly not be minimised, but I venture to join in the protest which is being ventilated in your columns against his condemnation of the Pirquet test. It so happens that, at an institution where I was previously assistant medical officer, a number of cases on which I had performed a Pirquet test were later tested by the Mantoux method by Dr. D'Arcy Hart. The number of cases tested by both methods was sufficient to enable me to compare the relative value of the two tests. In nearly every case the results of the Mantoux and the Pirquet agreed and were compatible with the clinical findings. Furthermore it has been my experience to see on more than one occasion a fairly marked local reaction accompanied by slight fever as a result of the Mantoux test, even in skilful hands. This has led me to prefer the Pirquet test, for any reaction which causes inconvenience to the patient is not justified in a test which may be, but is not always, of major clinical importance.

I am, Sir, yours faithfully,

M. C. WILKINSON.

Black Notley Sanatorium, Essex, April 9th, 1932.

CHRONIC DUODENAL STASIS.

To the Editor of THE LANCET.

SIR,—In the leading article on this subject in your last issue (p. 781) you refer to a paper[1] written by us two years ago in which we essayed to prove the existence of a syndrome in children owing its origin to a mild degree of duodenal obstruction from congenital arterio-mesenteric compression. Your mention of this work encourages us to state that we have recently made two additional observations which seem to support our thesis. In one case there was unequivocal evidence post mortem of congenital ileus; and in another we were fortunate enough to obtain radiographic evidence of duodenal stasis which we had hitherto failed to demonstrate. A second paper from us, dealing with this difficult subject, in which it is so necessary not to go further than the facts warrant, will appear in the April issue of the *Archives of Disease in Childhood.*

We are, Sir, yours faithfully,

REGINALD MILLER,

London, April 9th, 1932. H. COURTNEY GAGE.

---

[1] Arch. Dis. Child., 1930, v., 83.

CHELTENHAM HOSPITALS.—Last year the Cheltenham General and Eye Hospitals treated 2034 in-patients to a conclusion and attended to 9756 new out-patients. The average cost of each patient treated to a conclusion was £8 6s. 11½*d.*, and the weekly cost of each £2 16s. 4½*d.*, a small increase. Of the income of £19,609 (deficit £674) £7400 was derived from workers' contributions.

CORRESPONDENCE

THE GALL-BLADDER AND CARDIAC PAIN.

To the Editor of THE LANCET.

SIR,—I am delighted to find that Dr. C. H. Miller is calling attention to the association of cardiac pain with disease of the gall-bladder. The connexion is not yet generally appreciated. I propose in the near future to deal fully with my experience of the relation of gall-bladder infections to troublesome cardiac disease. It has been my lot on many occasions to find that "heart disease" has been the reason given for refusal of the benefits of surgical treatment to patients suffering from cholelithiasis. In such cases it is a common experience to find that removal of the gall-bladder is followed by a restitution of the heart to a normal condition, or by a very considerable measure of relief to cardiac symptoms. Sir James Mackenzie was first responsible for my interest in this subject, by asking me to operate upon a number of his "cardiac" patients. I removed the gall-bladder and the "heart disease" not seldom disappeared. Disease of the myocardium may often be regarded as the strongest indication for surgical measures. The relationship between infections of the gall-bladder and cardiovascular disease has hardly received the attention it deserves since Sir James Mackenzie and Sir Humphry Rolleston so clearly described it.

I am, Sir, yours faithfully,

Portland-place, W., April 11th, 1932. MOYNIHAN.

ADSORPTION OF IODINE BY ACTIVATED CARBON.

To the Editor of THE LANCET.

SIR,—The note by Mr. B. A. Adams in your issue of April 2nd (p. 724) is based on the following two assumptions, both of which, we submit, are open to considerable doubt.

1. That the prevalence of goitre is associated with the iodine content of water-supplies.
2. That water plays a material part in the supply of iodine to the human body.

The questions concerning iodine, its distribution and relationship to goitre, have recently been exhaustively studied by Dr. J. B. Orr and his co-workers at the Rowett Research Institute, Aberdeen, and two valuable reports incorporating their findings and tentative conclusions have been published by the Medical Research Council (Special Report Series No. 123, 1929, and No. 154, 1931). From these reports, which consider both the information accumulated to date from all parts of the world, and also the recent investigations by Dr. Orr in Great Britain, we learn :—

1. That analysis of the water from the supplies of a number of urban and rural areas in this country showed no correlation between the concentration of iodine in the water and the incidence of goitre in the area from which it came.
2. That the iodine content of water-supplies, especially surface waters (the most likely to be treated by activated carbon), is small compared with that of many foodstuffs.

The part generally played by drinking water in supplying iodine is very small and probably can be entirely neglected for, in a goitrous area, the deficiency of iodine in all the foodstuffs cannot be made good by that in the water, and in a non-goitrous area the amount of iodine in the water constitutes so small a proportion of the whole in all articles of diet that its absence would not be felt.

In our experience activated carbon has proved of great value in the removal of certain odours and tastes that occasionally appear in the river-derived water-supplies and which resist all other measures of treatment. In these cases, therefore, and in view of the information at present available concerning water-supplies, iodine and goitre, we are of opinion that activated carbon should not be withheld on account of its power of removing iodine. In view of the technique employed by Mr. Adams and the inaccuracy and indelicacy of all known methods for the estimation of iodine in water and foods, it is doubtful whether he is justified in arriving at the conclusion, that "all these forms of iodine were removed invariably and completely by treatment with activated carbon."

The function of a water authority is to supply an abundance of pure water which is colourless, odourless, and palatable, and the use of activated carbon may be necessary to produce these latter conditions. The supply to the human body of such essential substances as iodine, calcium, iron, vitamins, &c., is properly carried out by a well-arranged diet, and water-supplies are, as far as can at present be told, quite unimportant in these respects.

We are, Sir, yours faithfully,

JOHN F. BEALE,
ERNEST SUCKLING.

The Counties Public Health Laboratories, 91, Queen
Victoria-street, London, E.C., April 8th, 1932.

THE TOLL OF THE ROADS.

To the Editor of THE LANCET.

SIR,—It might well be supposed that members of the medical profession would have a particular interest in the prevention of unnecessary death and disablement, yet from the absence of further comment on this topic since the interesting letter from Dr. Galbraith on Jan. 23rd, it must be assumed that their attitude is the same as that of the general public, which apparently may be expressed as follows: (1) The number of road accidents is not excessive. (2) In the great majority if not in all cases, pedestrians, cyclists, or other non-motorists are to blame. (3) If occasionally a motor-car is at fault it is regrettable but inevitable, and is the natural price to pay for progress.

(1) is a matter of opinion ; the figures are published from time to time, and are now apparently upwards of 7000 killed and 177,000 injured per annum in Great Britain.

(2) is obviously absurd, for many accidents occur in which one or more motors alone are concerned, while many pedestrians are killed on the pavements. Further, it draws a line between motorists and pedestrians and suggests that the former are infallible, which is impossible ; for motorists are merely pedestrians in a position of responsibility for which they may be quite unfitted.

As regards (3), it would be interesting to hear the views of the medical profession on the propriety of regarding the mere multiplication of the means of mechanical transport as "progress," without regard for the need for this transport or the use to which it may be put.—I am, Sir, yours faithfully,

Carlton Hill, N.W., April 6th, 1932. R. JOHN CLAUSEN.

scarlet fever, and, on one occasion, he continued e debate over three weekly meetings." Dr. James lieved that hospitals tended to spread scarlet ver, and he was strongly against the massing of ildren in large public schools. He opposed medical spection of school-children by whole-time medical icers, preferring that the work should be done by e family practitioners. As he was physician to e schools of the Edinburgh Merchant Company s views led to a serious official situation. It was timately resolved by the company's agreement th the Scottish Education Department that the ork should be done by the medical officers of the hool board, and this system has been operative r over 20 years. He also had very definite views n tuberculosis, holding a theory that the Timothy ass bacillus was an active factor. He was always ady, at casual meetings, to argue the case. He as also keenly interested and well informed on ciological problems, and his occasional addresses howed that he was alive to the social aspects of edicine.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

Surg. Comdrs. H. M. Braithwaite and S. W. Grimwade re placed on the retd. list at their own request.

Surg. Comdr. D. H. C. Given is placed on the retd. list ith the rank of Surg. Capt.

Surg. Lt.-Comdr. (D) D. Paterson is placed on the retd. st with the rank of Surg. Comdr.

Surg. Lieut. T. L. J. Barry, to be Surg. Lt.-Comdr.

The following appointments are notified: Surg. Comdrs. V. J. Colborne to *Vivid* for R.N. Hospital, Plymouth, and H. M. Whelan to *Revenge*.

Surg. Lieut. Comdr. W. P. E. McIntyre to *President*.

Surg. Lt. S. R. G. Pimm to *Penzance*.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt. R. J. Matthews to be Surg. Lt.-Comdr.

Surg. Sub-Lt. R. M. Marshall to be Surg. Lt.

Proby. Surg. Sub-Lt. D. R. Hughes to be Surg. Sub-Lt.

ROYAL ARMY MEDICAL CORPS.

Maj. H. S. Blackmore, Res. of Off., R.A.M.C., relinquishes his appt. under Art. 520 (b), Royal Warrant for Pay and Promotion, 1831.

Maj. R. W. Chapman retires, receiving a gratuity.

TERRITORIAL ARMY.

Capt. H. V. Morlock resigns his commn.

Lts. C. R. L'E. Orme and J. G. Weston to be Capts.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Lt.-Col. T. P. Puddicombe, having attained the age limit retires and retains his rank, with permission to wear the prescribed uniform.

INDIAN MEDICAL SERVICE.

The undermentioned officers relinquish their temp. commns.: Capts. R. C. Goulatia and S. K. Ganguli.

ROYAL AIR FORCE.

Flying Officer Hyman Ruben Clein is promoted to the rank of Flight Lieutenant.

RESERVE OF AIR FORCE OFFICERS.

Flight-Lt. J. J. Quinlan relinquishes his commission on appointment to a commission in the Indian Medical Service.

THE COLONIAL SERVICE.

Dr. E. V. W. Mellard is appointed Surgeon at Jamaica; Dr. C. H. Howat, District Medical Officer at Cyprus; Dr. J. S. Cramer, Supernumerary Medical Officer, Leeward Islands; Dr. H. B. Boucher, Medical Officer, Gambia; Dr. J. W. Murdoch, Medical Superintendent Central Mental Hospital, Federated Malay States; and Dr. A. H. Owen, Director of Medical and Sanitary Services, Tanganyika Territory.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

RESTRICTION OF THE PRACTICE OF MEDICINE BY FOREIGNERS.

THE disquieting influx of foreign medical students and doctors into France, to which I have referred from time to time, has culminated in protective legislation which is likely to put a most effective barrier to future invasions of this kind. A Bill dealing with this problem was passed on Feb. 29th by the Chamber of Deputies without discussion. As it had already been approved by the Senate, there is no prospect of its being set aside. It remains, however, to be seen how far its conditional clauses will react to the circumstances of individual cases. According to the first article, no one may practise medicine in France unless he is a French subject or a native of a French Protectorate. Nor may he practise medicine without a State diploma. But in the case of those countries in which French doctors are allowed to practise, applications may be made to the French Government for dispensation in certain instances from the obligation of becoming a naturalised Frenchman. With regard to such countries, it is presumed that an equilibrium will be established in the sense that approximately as many Frenchmen as foreigners are allowed to practise in each other's countries. The second article concerns the preliminary studies and examinations which may be made obligatory on newcomers even if they already possess the medical diploma of some other country. As for the foreign medical student, the third article rules that no exemption from preliminary studies shall be made, however prolonged his studies abroad may have been. In the fourth article, surgeon-dentists with foreign diplomas are obliged, if they wish to practise in France, to pass the same examinations that are required of French students seeking a diploma in dentistry. Not more than a year of preliminary studies can be dispensed with by the would-be surgeon-dentist. As for the foreign doctors and dentists already practising in France, they must submit their diplomas for verification within three months.

AMALGAMATING EDINBURGH HOSPITALS.—A meeting of the subscribers to the Edinburgh Royal Maternity and Simpson Memorial Hospital recently unanimously agreed to the amalgamation of the institution with the Edinburgh Royal Infirmary. The agreement will require the sanction of Parliament. Last year the Simpson Hospital dealt with over 44 per cent. of the births in Greater Edinburgh, and 3467 cases were attended. The building of a new hospital on the site of George Watson's College will shortly be begun.

DONATIONS AND BEQUESTS.—Mr. Edwin Hoyle, of Old Hall Hotel, Buxton, Derbyshire, bequeathed £1500 to Ancoats Hospital and Ardwick and Ancoats Dispensary, Manchester; £1000 to St. Mary's Hospitals, Manchester; £500 to Henshaw's Institution for the Blind, Manchester; £500 to St. Dunstan's Hostel; £300 to the Devonshire Hospital, Buxton; £200 to the Dental Hospital, Manchester; £200 to Manchester and Salford Blind Aid Society; £100 to the Buxton and District Cottage Hospital; and the residue of the property as to one-fifth to the Royal National Lifeboat Institution, and four-fifths to the Manchester Royal Infirmary and Dispensary.—Mrs. Margaret Brown Cade, Kingston, left by will £1000 to Hull Royal Infirmary, and £500 to Hull and Sculcoates Dispensary.—The late Mr. Edward Brake, of Bath, left, on his wife's death, £1000 to the Royal Bath United Hospital, and £1000 to the Cancer Fund of the Middlesex Hospital, London.

OBITUARY

ALEXANDER L. URQUHART, M.B. Edin.,

PROFESSOR OF PATHOLOGY IN THE EGYPTIAN UNIVERSITY.

THE Faculty of Medicine of the Egyptian University has suffered a severe blow in the loss of its professor of pathology, Prof. A. L. Urquhart, whose death we announced last week.

Alexander Lewis Urquhart, son of the late Dr. A. R. Urquhart, of Perth, was born on April 15th, 1887. He was educated at Edinburgh Academy and thence proceeded in 1906 to the University of Edinburgh, where he was at first more marked out by his proficiency at games than at work, being a full exponent of football, cricket, and golf, especially the first. In 1911 he graduated as M.B., and in the same year entered the Royal Army Medical Corps. Between then and the outbreak of war he served for most of the period as demonstrator in the R.A.M.C. College at Millbank, and while thus employed he obtained the D.P.H. diploma of the Conjoint Board. Soon after the commencement of the war he was sent to France in command of a motor ambulance convoy. After a short time in this position he was transferred to the Macedonian front in charge of the main pathological laboratory, and was twice mentioned in despatches. For his services in the war he was awarded the O.B.E.

On his return to England in 1919 he was offered by Prof. L. S. Dudgeon, under whom he had worked in Macedonia, a post in the pathological department of St. Thomas's Hospital, and severing his connexion with the R.A.M.C. he accepted the offer. From then till 1927 he acted as lecturer in pathology at St. Thomas's Hospital, and Curator of the Museum. But in 1927 he was offered and accepted the chair of Pathology in the Faculty of Medicine of the Egyptian University. In this post he was an immediate success, as the following testimony from a colleague shows. "To an excellent knowledge of his subject Urquhart added the fruits of a wide and varied experience. As a teacher none could have been more patient and painstaking. He inspired his staff with an enthusiasm for teaching and research which will remain for long years as a memorial of his work in Egypt. Gentle, generous, and kindly in nature, he deeply endeared himself to all his colleagues, both English and Egyptian. His students revered him for his knowledge and repaid him with their whole-hearted affection for his devotion to them. Perhaps the most dominant feature of his character was his friendliness and his capacity for making friends. Of these, and their name is legion, each one will confess that a more sweet and lovable character could scarcely be found. His death at the early age of 44 leaves an aching void in the hearts of all who knew him."

Prof. Urquhart was not a prolific writer, but his contributions to medical literature were characterised by a very high degree of painstaking accuracy. Probably his most important articles were a review of the Serological and Morphological Characteristics of the Pneumococcus in the *Journal of the Royal Army Medical Corps* (1922) and a joint study of Bacillary Dysentery in the British Forces in Macedonia published for the Medical Research Committee.

He married in 1915 Anne, daughter of the late Mr. D. F. Addis, formerly of the Indian Civil Service. They had one son, born in 1920. He died in the evening of March 28th, and was buried, with full military honours, on the following afternoon in the British Protestant Cemetery, Old Cairo.

HENRY HARVEY M.B. Edin.

Dr. Harvey, who has died in Liverpool in his eighty-fifth year, was widely esteemed as a practitioner in the city where he had spent most of his life. Born at Milton in Kent, the son of Jacob Harvey, he was educated at Liége in Belgium and at Edinburgh, where he qualified in 1870. He went to Liverpool in the following year as house surgeon at the Liverpool Southern and Toxteth Hospital, and at the time of his death he was the only human link between that institution and the Royal Southern Hospital to which his services were transferred on the reorganisation in 1872. On completing his resident appointment in 1873 he took up general practice in the Wavertree district, becoming medical officer of health for Wavertree, and subsequently for Childwall. As a general practitioner interested in both medicine and general surgery he was well acquainted with the professional life of Liverpool. "It is a pity," writes one of his medical friends, "that he did not write biographical sketches to place in the archives of the Liverpool Medical Institution, for he was a man of literary culture whose style was one of interesting narrative. In course of conversations with him one learnt much about the conditions, more especially of surgical practice, in the days when antiseptic surgery was in its infancy, and when faulty technique accounted for much scepticism concerning Lister's teaching. It was always interesting to meet him, because his knowledge embodied the best of the old methods of therapeusis, so many of which have unfortunately been forgotten or remain untaught, together with the modern methods of treatment in which he was well versed. He was a thoroughly sound practitioner, trusted and respected by all with whom he came in contact. His kindly, thoughtful face and gentleness of manner, together with his keen personal interest in his patients, were, in themselves, assets which promoted their well being. Of him it might truly be said, 'He is gentil that doth gentil dedis.'"

ALEXANDER JAMES, M.D., F.R.C.P., F.R.S. Edin.

EDINBURGH has lost a distinguished physician by the death of Dr. Alexander James, at the age of 81. He belongs to the generation that included Prof. Grainger Stewart, Dr. Claud Muirhead, Prof. Wylie, and Mr. "Joe" Bell. Graduating in 1872, he studied abroad at Leipzig, and returned to become lecturer on the practice of medicine in the extra-mural school at Edinburgh. In due course he was appointed physician to the Royal Infirmary, where he was a popular clinical teacher. A colleague writes of him that he was an engaging personality and secured the devotion of his students. "He had a good speculative mind, and was ready for controversy at a moment's notice; but he made no enemies. He took strong views, but he always retained his genial temper. At the local branch of the British Medical Association and at the Medico-Chirurgical he would bring up problems like the effect of hospitals on the spread scarlet fever, and, on one occasion, he continued .e debate over three weekly meetings." Dr. James lieved that hospitals tended to spread scarlet ver, and he was strongly against the massing of ildren in large public schools. He opposed medical spection of school-children by whole-time medical ficers, preferring that the work should be done by ie family practitioners. As he was physician to he schools of the Edinburgh Merchant Company is views led to a serious official situation. It was ltimately resolved by the company's agreement ith the Scottish Education Department that the ork should be done by the medical officers of the hool board, and this system has been operative r over 20 years. He also had very definite views n tuberculosis, holding a theory that the Timothy rass bacillus was an active factor. He was always eady, at casual meetings, to argue the case. He as also keenly interested and well informed on ociological problems, and his occasional addresses howed that he was alive to the social aspects of nedicine.

OBITUARY

ALEXANDER L. URQUHART, M.B. Edin.,

PROFESSOR OF PATHOLOGY IN THE EGYPTIAN UNIVERSITY.

The Faculty of Medicine of the Egyptian University has suffered a severe blow in the loss of its professor of pathology, Prof. A. L. Urquhart, whose death we announced last week.

Alexander Lewis Urquhart, son of the late Dr. A. R. Urquhart, of Perth, was born on April 15th, 1887. He was educated at Edinburgh Academy and thence proceeded in 1906 to the University of Edinburgh, where he was at first more marked out by his proficiency at games than at work, being a full exponent of football, cricket, and golf, especially the first. In 1911 he graduated as M.B., and in the same year entered the Royal Army Medical Corps. Between then and the outbreak of war he served for most of the period as demonstrator in the R.A.M.C. College at Millbank, and while thus employed he obtained the D.P.H. diploma of the Conjoint Board. Soon after the commencement of the war he was sent to France in command of a motor ambulance convoy. After a short time in this position he was transferred to the Macedonian front in charge of the main pathological laboratory, and was twice mentioned in despatches. For his services in the war he was awarded the O.B.E.

On his return to England in 1919 he was offered by Prof. L. S. Dudgeon, under whom he had worked in Macedonia, a post in the pathological department of St. Thomas's Hospital, and severing his connexion with the R.A.M.C. he accepted the offer. From then till 1927 he acted as lecturer in pathology at St. Thomas's Hospital, and Curator of the Museum. But in 1927 he was offered and accepted the chair of Pathology in the Faculty of Medicine of the Egyptian University. In this post he was an immediate success, as the following testimony from a colleague shows. "To an excellent knowledge of his subject Urquhart added the fruits of a wide and varied experience. As a teacher none could have been more patient and painstaking. He inspired his staff with an enthusiasm for teaching and research which will remain for long years as a memorial of his work in Egypt. Gentle, generous, and kindly in nature, he deeply endeared himself to all his colleagues, both English and Egyptian. His students revered him for his knowledge and repaid him with their whole-hearted affection for his devotion to them. Perhaps the most dominant feature of his character was his friendliness and his capacity for making friends. Of these, and their name is legion, each one will confess that a more sweet and lovable character could scarcely be found. His death at the early age of 44 leaves an aching void in the hearts of all who knew him."

Prof. Urquhart was not a prolific writer, but his contributions to medical literature were characterised by a very high degree of painstaking accuracy. Probably his most important articles were a review of the Serological and Morphological Characteristics of the Pneumococcus in the *Journal of the Royal Army Medical Corps* (1922) and a joint study of Bacillary Dysentery in the British Forces in Macedonia published for the Medical Research Committee.

He married in 1915 Anne, daughter of the late Mr. D. F. Addis, formerly of the Indian Civil Service. They had one son, born in 1920. He died in the evening of March 28th, and was buried, with full military honours, on the following afternoon in the British Protestant Cemetery, Old Cairo.

HENRY HARVEY M.B. Edin.

Dr. Harvey, who has died in Liverpool in his eighty-fifth year, was widely esteemed as a practitioner in the city where he had spent most of his life. Born at Milton in Kent, the son of Jacob Harvey, he was educated at Liége in Belgium and at Edinburgh, where he qualified in 1870. He went to Liverpool in the following year as house surgeon at the Liverpool Southern and Toxteth Hospital, and at the time of his death he was the only human link between that institution and the Royal Southern Hospital to which his services were transferred on the reorganisation in 1872. On completing his resident *appointment in 1873 he took up general* practice in the Wavertree district, becoming medical officer of health for Wavertree, and subsequently for Childwall. As a general practitioner interested in both medicine and general surgery he was well acquainted with the professional life of Liverpool. "It is a pity," writes one of his medical friends, "that he did not write biographical sketches to place in the archives of the Liverpool Medical Institution, for he was a man of literary culture whose style was one of interesting narrative. In course of conversations with him one learnt much about the conditions, more especially of surgical practice, in the days when antiseptic surgery was in its infancy, and when faulty technique accounted for much scepticism concerning Lister's teaching. It was always interesting to meet him, because his knowledge embodied the best of the old methods of therapeusis, so many of which have unfortunately been forgotten or remain untaught, together with the modern methods of treatment in which he was well versed. He was a thoroughly sound practitioner, trusted and respected by all with whom he came in contact. His kindly, thoughtful face and gentleness of manner, together with his keen personal interest in his patients, were, in themselves, assets which promoted their well-being. Of him it might truly be said, 'He is gentil that doth gentil dedis.'"

ALEXANDER JAMES, M.D., F.R.C.P., F.R.S. Edin.

Edinburgh has lost a distinguished physician by the death of Dr. Alexander James, at the age of 81. He belongs to the generation that included Prof. Grainger Stewart, Dr. Claud Muirhead, Prof. Wylie, and Mr. "Joe" Bell. Graduating in 1872, he studied abroad at Leipzig, and returned to become lecturer on the practice of medicine in the extra-mural school at Edinburgh. In due course he was appointed physician to the Royal Infirmary, where he was a popular clinical teacher. A colleague writes of him that he was an engaging personality and secured the devotion of his students. "He had a good speculative mind, and was ready for controversy at a moment's notice; but he made no enemies. He took strong views, but he always retained his genial temper. At the local branch of the British Medical Association and at the Medico-Chirurgical he would bring up problems like the effect of hospitals on the spread had been told of numbers of cases where there was tinct evidence of deterioration in the children's alth. He was sure that this was not the wish of the nister of Labour, but it was certainly happening. had had complaints from private organisations ich had had certain funds that they were having spend those funds for such things as additional lk. This was a very serious thing. Further an that the action of some of the public assistance mmittees was such as to lead the men in the district believe that if they got the maximum transitional nefit in no circumstances would they get poor-law lief as well. The maximum was 33*s.* 3*d.* for a man d wife and five children, and they could not live that sum. (Hear, hear.) This condition of things ould result in a dreadful deterioration in the health d physique and morale of the country and in the d the State would have to pay for that.

After further debate the resolution was agreed to

PUBLIC HEALTH SERVICES.

On Tuesday, April 12th, on the motion that the ouse of Commons should go into Committee of pply on the Civil Service Estimates, Dr. MORRIS-ONES called attention to local government administra-on and moved "that this House appreciates the ogress made by local authorities since the passing the Local Government Act of 1929 in coördinating d improving their public health services and, while cognising the need for economy in local expenditure, of opinion that the development of these services hould steadily continue as and when circumstances ermit.". After debate,

Sir E. HILTON YOUNG (Minister of Health) said hat there was no foundation for the suggestion that here had been any unwise restriction of the public ealth services in the interests of economy. It was he policy of the Government, as it would be of any overnment, to consider public health as a matter of rgent national importance, and they held that conomy would be false if it resulted in reducing the fficiency of those essential services.

The motion was withdrawn.

HOUSE OF COMMONS.

TUESDAY, APRIL 5TH.

Slum Clearance.

Mr. ALBERY asked the Minister of Health if he could make a statement on the progress of slum clearance and the future intentions of the Government.—Mr. ERNEST BROWN (Parliamentary Secretary to the Ministry of Health) replied: Up to the 31st March last my right hon. friend had received resolutions declaring 408 areas in England and Wales, the clearance of which involves the displacement and re-housing of approximately 68,000 persons, to be clearance areas under the Housing Act, 1930, and 269 clearance or compulsory purchase orders had been submitted in connexion with such areas. Upwards of 13,000 houses, which are either earmarked or available for the purposes of the Act, have either been erected or are under construction. The intention is that local authorities should continue to make the fullest possible use of their powers in this matter.

WEDNESDAY, APRIL 6TH.

Hospitals and Motor Accidents.

Sir JOHN HASLAM asked the Minister of Transport if he had any information to give to the House as to the cost to the hospitals of the country during 1931 of treating motor accident cases; and what proportion of such cost had been recovered by them under the Road Traffic Act.—Mr. PYBUS replied: I regret that I am not in possession of the information asked for.

Sir J. HASLAM: Will the Minister make inquiries, because those of us who are interested in hospitals know that the receipts are infinitesimal as compared with the cost to the hospitals, and we fully expected a different state of affairs when the Bill was passed last session.

Mr. PYBUS: I am entirely sympathetic with the hon. gentleman, but as he will appreciate the information is very difficult to procure. However, I will try again.

Sir J. NALL: Could not my right hon. friend ask the police authorities to send the accident cases to the poor-law hospitals, which are in a position to make charges, rather than impose them on the voluntary hospitals.

Maternal Mortality.

Mr. RHYS DAVIES asked the Minister of Health whether the departmental committee on maternal mortality had finished their deliberations; and when would their final report be published.—Mr. ERNEST BROWN replied: My right hon. friend understands that this committee are now considering their final report, which is expected to be ready for publication towards the end of the summer.

Imports of Bacon from Lithuania.

Mr. PRICE asked the Minister of Health where the imports of bacon from Lithuania and Poland were examined; whether the bacon was imported chemically cured or smoked; and what quantity was rejected as unfit for *human food in the 12 months ended* Dec. 31st, 1931.—Mr. ERNEST BROWN replied: Bacon is consigned from Lithuania and Poland to Bermondsey and Hull. It may be examined there and at other ports to which it is tran-shipped, such as Liverpool and Newcastle. It is brine-cured, in accordance with the regulations of the Ministry of Agriculture and Fisheries. My right hon. friend regrets that he cannot state separately the total quantity of bacon from these particular countries which has been condemned.

Antenatal Clinics in London.

Mr. RHYS DAVIES asked the Minister of Health the number of antenatal clinics which had been approved by the Ministry up to date in London, the county boroughs, and the counties, giving the number of municipal and voluntary centres, the number of separate sessions in each division, and the number of sessions held on the same day as the infant consultations were held.—Sir E. HILTON YOUNG replied: The approval of my department is not now required to the establishment of antenatal clinics. The *returns for the year 1930, the latest* year for *which complete* information is at present available, show that at the end of that year the number of antenatal clinics maintained by local authorities and by voluntary associations in London, and in the county boroughs and counties in England and Wales, and the number of sessions held during the year, were as follow:—

—	Number of antenatal clinics maintained by—		Number of sessions at all antenatal clinics during 1930.
	Local authorities.	Voluntary associations.	
England—			
London	52	66	8,165
County boroughs	242	58	19,599
Counties	560	70	17,668
Totals ..	854	194	45,432
Wales—			
County boroughs	9 } 53	—	804 } 1,543
Counties	44 }		739 }
Grand totals ..	907	194	46,975

Information is not available as to the number of sessions held at the municipal and voluntary clinics, respectively, in England, or as to the number of sessions held on the same day as the infant consultations are held.

Food Consumption in Britain.

Mr. THOMAS WILLIAMS asked the Minister of Agriculture approximately the proportion of food for human consumption produced in this country and imported from abroad during 1931.—Sir J. GILMOUR replied: The latest available figures are those contained in the report on the Agricultural Output and Food Supplies of Great Britain, published by the Ministry of Agriculture and Fisheries in 1929. These estimates were based chiefly on the years 1924–27, and showed that in the case of foodstuffs (including fish) normally produced in Great Britain the value of the *home production* was 44·9 per cent. of the total. The comparable figure for all foodstuffs was 39·3 per cent. Similar calculations will, it is hoped, be made in connexion with the agricultural and industrial censuses for 1930, but the results cannot be available for some considerable time.

THURSDAY, APRIL 7TH.

Disability Pensions.

Major LEIGHTON asked the Minister of Labour the number of men drawing disability pension registered as unemployed at the labour exchanges.—Sir H. BETTERTON replied: At Feb. 22nd, 1932, the latest date for which figures are

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

UNEMPLOYMENT BENEFIT AND PUBLIC HEALTH.

THE House of Commons, which reassembled after the Easter Recess on Tuesday, April 5th, went the same day into Committee on the financial resolution in connexion with the Transitional Payments (Unemployed Persons) Bill. Captain BOURNE, Deputy-Chairman of Committees, was in the chair.

Sir HENRY BETTERTON (Minister of Labour) in moving the resolution, said its objects were twofold. The first was that the power to make transitional payments to persons who had not paid 30 contributions in the past two years should be extended to June 30th, 1933; and the second was that the cost of this extension should be met by the Exchequer. Those persons who were now in receipt of transitional payments would cease to receive them so soon as their benefit period expired; and supposing that there were no new legislation they would begin to run off immediately after April 18th next. If, therefore, the power to make transitional payments beyond that date was to continue this Bill must be passed in the interim. The reason why the Bill provided that the period should be extended to June 30th, 1933, was that in June of next year the Act—or any how the material parts of it—which was passed by the Labour Government expired, and the anomalies Act passed by the Labour Government also expired on the same date. Therefore, before that time there must be new legislation dealing with the whole question. The Royal Commission set up by the Labour Government were considering what arrangements were to be made outside the insurance scheme for the able-bodied unemployed, and that must include the whole position of those now affected by transitional payments. The Bill connected with this financial resolution was therefore a temporary carrying-over measure pending legislation which would in any case be necessary next year. The cost to the Exchequer up to June 30th, 1933, was estimated to be about £20,000,000. There had been a reduction in the numbers of the unemployed of 134,000 compared with a month ago. This was the first time for over two years in which the figures had been less than they were a year before and they had to go back to December, 1929, to find a figure which was less than the corresponding period of a year ago. He thought that these figures justified the hope that when world conditions improved and economic chaos was replaced by ordered progress, this country would be among the first nations of the world to take advantage of that improvement.

OPERATION OF THE MEANS TEST.

Mr. LAWSON said that not only were the Government pushing this financial responsibility back upon the poor-law, but they were pushing it back upon the poorest families. The operation of the means test was inflicting upon great masses of the people the most disgraceful pains and penalties, amounting almost to poverty of the worst kind. He had seen a letter in the newspapers that had been received by one of the Members of the House from one of the chief doctors in one of the great hospitals of Newcastle in which there was a request that the Member should use his influence to put an end to the means test because in his own experience the doctor had had daily proof of the fact that the means test was playing havoc with the physique and the general life of the people with whom he came in contact. He (Mr. Lawson) had always been willing to give credit for the great kindness of people generally, but nevertheless he said deliberately that whether they meant it or not a great section of the well-to-do in this country had been callous concerning the application of the means test to the great masses of the people. That was the more significant when one noted that for every pound asked for on the money market it was possible to get £50 from those desirous of subscribing. After all the real problem facing the present or any other Government was to get rid of unemployment. The Government might succeed in passing this Bill, but as far as the Labour party was concerned they were in favour of ending the means test root and branch without equivocation or qualification. *It was also time that the Government* should realise clearly that if men could not get work it was their duty to maintain them in an adequate and decent way.

Mr. MACMILLAN said that the maintenance of the unemployed had to be carried through on economical lines now and in the future, not because any Member of the House thought that 15*s.* 3*d.* per week was a sufficient sum for a man to live upon, but because too great a strain upon public expenditure might make it impossible to pay such people any sum at all. Nevertheless it was true, whoever might be responsible for the present difficulties, that a Government which asked people to be patient under hardships must satisfy them that every step was being taken to deal with the conditions and circumstances which had made those hardships necessary. He thought that the National Government had made a good start.

THE POVERTY LINE OF SUBSISTENCE.

Mr. A. BEVAN said that they ought not to keep hundreds of thousands of people on the poverty line of subsistence. Some time ago a medical investigation was conducted in the county of Monmouth and all the children in 10 schools were examined for malnutrition. They were examined as regarded weight, for height, anæmia, poor toneless skin, lack of subcutaneous tissue, dry hair, lacking lustre, tired expression, and listless attitude. The children were compared, not with children belonging to the higher classes, but with children in the rural areas of the county. There was no difference of race. The graph for each age-group of children showed a downward curve in the schools situated in the areas where unemployment had been continuous as compared with the graph of children in the rural areas. In the age-group 11–12 years the children were on the average 4 lb. lighter in weight; in the age-group 12–13 nearly 6 lb. lighter in weight: in the age-group 13–14—children who were born when the industrial depression started—the difference in weight was 7¾ lb. In every case the weight of the child was infinitely lower than the average weight for the whole country. In the matter of height the same story was told. The medical officers' report was open for public inspection and the facts spoke for themselves. The difference in height was, in some cases, half an inch, three quarters of an inch, five inches, three inches, and four inches. Yet the Ministry of Health and the Ministry of Labour said that these children were too fat and that they must sacrifice another few pounds in weight in order to keep the National Government in office.

DETERIORATION IN CHILDREN'S HEALTH.

Mr. BRIANT asked the Minister whether, considering that the present position had to continue for another 15 months, it was not possible to issue some regulations which, while not affecting the general administration of the unemployment fund, would assist its smoother operation. He believed that the means test was justified but in practice it was often found to be carried out extremely unfairly. The Charity Organisation Society was considered by some people to be rather hard, but his information from many of its most experienced members was that there was beginning to be a distinct reduction in the balance which was available for even the ordinary care of children.

ore being landed here so as to prevent their being a possible se of typhoid if used for human consumption.—Mr. E. own replied: No special regulations have been made by department with regard to imported shell-fish, but the h Free State Government have made regulations hibiting the distribution for sale for human consumption shell-fish taken from layings in a defined area in the nties of Louth and Meath, unless the shell-fish have been shed and relaid. My right hon. friend is not aware that similar regulations have been made applying to other ings in the Irish Free State.

Lotteries and Sweepstakes.

Sir William Davison asked the Prime Minister whether would be provided in the terms of reference to the Royal mmission which the Government purposed to set up inquire into the law relating to lotteries, &c., that it was sirable that a report on the matter should be presented thin a period not exceeding four months so that the isting anomalies of the law relating to lotteries might be nedied without delay; and whether the Government d definitely decided that, pending the Report of the yal Commission, no facilities were to be given for the ther stages of the Lotteries Bill, ordered by the House Commons to be brought in on March 22nd.—Mr. acDonald replied: The terms of reference of the Royal ommission are under consideration. It would be practicable to suggest any time limit within which the ommission are to report, but I have no doubt that they will deavour to expedite their inquiry so far as the complexity the issues involved will permit. It would be within the scretion of the Commission to submit interim reports ould they consider it expedient to do so. Pending the ceipt of their report it would be inappropriate, I think, r legislation to proceed on one aspect of the problem which ey are to investigate.

Unemployed Persons and Poor Relief.

Mr. Rhys Davies asked the Minister of Health the oportion of persons receiving unemployment benefit and ansitional benefit payments, respectively, who were also receipt of poor relief.—Sir E. Hilton Young replied: t the beginning of February, 1932, approximately 1 per ent. of the persons with claims authorised for insurance enefit, and 1·9 per cent. of those with applications authorised r transitional payments, were in receipt of poor relief. hese particulars relate to England and Wales only.

Mr. Rhys Davies asked the Minister of Health the total umber of men and women, and their dependants, espectively, receiving poor relief due to unemployment.—ir E. Hilton Young replied: During the month of ebruary, 1932, the average numbers of unemployed men nd women (and their dependants) ordinarily engaged in ome regular occupation who were in receipt of poor relief n England and Wales were: men, 83,398; women, 5145; ependant wives and children, 205,499.

Mr. Hornby asked the Minister of Labour if he was aware hat owing to the action of courts of referees in disqualifying persons in the transitional class from insurance benefit many persons had had to seek public assistance, and that this number was increasing, causing a burden on the rates of many cities and towns; and whether he was prepared to promote legislation making poverty arising from unemployment a national charge.—Sir Henry Betterton replied: No, Sir. I have no evidence that what my hon. friend suggests is taking place. The courts of referees have to decide, in cases of doubt and subject to appeal to the umpire, whether an applicant is normally in an insured trade; this condition has remained unchanged since transitional benefit was first instituted in 1928.

TUESDAY, APRIL 12TH.

Imports of Manchurian Partridges.

Mr. J. P. L. Thomas asked the Minister of Health whether he was aware that Manchurian partridges were being imported at the present time into Great Britain; and whether he was satisfied that the conditions under which these birds were trapped and transported were such that their sale in this country complied with the provisions governing the purity of food-supplies.—Mr. E. Brown replied: My right hon. friend understands that very few of these birds have been imported recently into this country. He has no definite information as to the conditions under which they are trapped and transported, but they are subject to inspection at the ports in this country under the Public Health (Imported Food) Regulations.

Cottage Hospital Costs.—Last year the Lyme Regis and District Cottage Hospital admitted 188 in-patients who cost on the average £3 15s 1½d. per week, a reduction of 5s. 6d. on the preceding years.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 2ND, 1932.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 95 (last week 41); scarlet fever, 1435; diphtheria, 815; enteric fever, 19; acute pneumonia (primary or influenzal), 1662; puerperal fever, 49; puerperal pyrexia, 104; cerebro-spinal fever, 69; acute poliomyelitis, 5; acute polio-encephalitis, 1; encephalitis lethargica, 16; dysentery, 15; ophthalmia neonatorum, 96. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on April 5th–6th was as follows: Small-pox, 121 under treatment, 4 under observation (last week 115 and 10 respectively); scarlet fever, 1390; diphtheria, 1432; enteric fever, 12; measles, 2757; whooping-cough, 435; puerperal fever, 30 (plus 13 babies); encephalitis lethargica, 226; poliomyelitis, 4; "other diseases," 131. At St. Margaret's Hospital there were 8 babies (plus 5 mothers) with ophthalmia neonatorum.

Deaths.—In 117 great towns, including London, there was 1 death from small-pox, 2 (1) from enteric fever, 114 (65) from measles, 4 (2) from scarlet fever, 46 (7) from whooping-cough, 30 (5) from diphtheria, 51 (9) from diarrhœa and enteritis under two years, and 158 (27) from influenza. The figures in parentheses are those for London itself.

Worcester reports the only death from enteric fever outside London. The fatal case provisionally classified to small-pox occurred in Deptford Metropolitan Borough. Deaths from influenza are sharply declining, the largest total being reported from Bristol with 13, followed by Sheffield with 7. Ten of the fatal cases of measles were reported in Liverpool, 5 each in West Ham and Portsmouth. There were 4 deaths from whooping-cough in West Ham and in Liverpool. Diphtheria accounted for 5 deaths in Liverpool, 4 in Hull.

The number of stillbirths notified during the week was 313 (corresponding to a rate of 47 per 1000 births), including 51 in London.

Fatal Case of Small-pox.—This case which occurred in Deptford was, Dr. F. L. Keith tells us, that of an unvaccinated infant, 3 weeks old at death. The child was infected during the first three days after birth, contracting the disease from her sister who had been in contact with other cases at school. The cause of death was given in the certificate as (*a*) pyæmia, (*b*) small-pox.

Walsall Contributory Scheme.—Under the terms of the contributory scheme which it is proposed to establish for Walsall General Hospital the following are eligible for membership: (1) married persons whose income does not exceed £312 per annum; (2) unmarried persons, widows, and widowers whose income does not exceed £250; (3) unmarried persons, widows, and widowers, whose income does not exceed £312, but who have relatives dependent on them; (4) young persons between the age of 14 and 16. Dependents of Classes 1 and 3 are also eligible for treatment. The contributions in Classes 1 and 3 are 3*d.* per week: Class 2, 2*d.* per week; Class 4, 1*d.* per week. Employers are invited to add a subscription of not less than one-third of their employees' contributions. The hospital's present income is £15,000, it spends £18,000, and needs £20,000.

Orthopædic Hospitals.—At the Manfield Orthopædic Hospital, Northampton, the average stay of a patient last year was 232 days at a cost of £83 13*s.* 8*d.* Dr. J. M. Mackintosh, the county medical officer, states that 70 per cent. of the patients become wage earners, and that "the quality of the treatment and the nursing are unsurpassed in this country."—The Wingfield Orthopædic Hospital at Headington, Oxford, which serves Berkshire, Buckinghamshire, and Oxfordshire, has been renamed the "Wingfield-Morris" Hospital in recognition of the generosity of Sir William Morris in undertaking to defray the entire cost (£70,000) of the new building. The old hospital consisted of temporary wooden buildings. The reconstruction scheme includes 140 beds, nurses' quarters with 50 rooms, a trainees' hostel for 22, and complete new workshops.

available, there were 43,674 ex-Service men in receipt of disability pensions on the registers of employment exchanges in Great Britain.

Economies and the Means Test.

Mr. LOGAN asked the Minister of Labour the total amount of savings effected as a result of the working of the Anomalies Act up to the latest available date.

Mr. THOMAS WILLIAMS asked the Minister of Labour how many applications for transitional benefit had been dealt with by public assistance committees; and what was the estimated saving effected by the imposition of the means test in this connexion.—Sir H. BETTERTON replied: The weekly benefit paid to persons on the live register at the end of February, after allowing for the reduction in the rates of benefit, was about £185,000 less than would have been paid in respect of the same number of persons on the live register before the introduction of the Anomalies Regulations and the Needs Test. This saving is at the rate of about £9,500,000 a year, of which roughly £2,000,000 may be attributed to the Anomalies Regulations and £7,500,000 to the Needs Test. There was, in addition, a saving in respect of persons who, on ceasing to draw benefit or transitional payments, discontinued registration without finding employment; while it is difficult to estimate this further saving precisely, I am satisfied that the total saving is at least as much as that estimated in the White Paper (Cmd. 3952) issued in connexion with the Economy Bill. As regards the first part of the question by the hon. Member for Don Valley, between Nov. 12th, 1931, and Feb. 20th, 1932, 3,212,862 applications for transitional payments were submitted to public assistance committees in Great Britain for determination. This number included 1,421,484 initial applications, and 1,791,378 renewal applications.

Free Meals for School-children.

Mr. THORNE asked the President of the Board of Education if he had any information as to the number of children receiving free meals from the various local educational authorities throughout the country for the period Nov. 1st to the nearest available date.—Sir DONALD MACLEAN replied: During the week ended Nov. 7th last approximately 113,000 children received free meals, including milk meals, under arrangements made by local education authorities in England and Wales. For the week ended March 12th last, the latest date for which complete figures are available, the corresponding figure was 139,000.

Poor-law Relief.

Mr. LUNN asked the Minister of Health what was the total number of men and women on poor-law relief at the end of July, 1931; and what was the total at the end of March, 1932, or up to the latest date available.—Sir E. HILTON YOUNG replied: Exact figures cannot be given, but it is estimated that approximately 284,000 men and 366,000 women were in receipt of relief at the end of July, 1931, and approximately 348,000 men and 448,000 women at the end of March, 1932.

Mr. THORNE asked the Minister of Health the number of persons in receipt of poor-law relief from Oct. 1st, 1931, to March 31st, 1932.—Sir E. HILTON YOUNG replied: The returns made to my department show the number of persons in receipt of poor relief on particular days, and not the number of persons who received poor relief during a period. The following is a statement as to the number of persons in receipt of poor relief in England and Wales on the last Saturday in each month from September, 1931, to March, 1932:—

September, 1931 ..	1,005,813	January, 1932 ..	1,188,628
October, ,, ..	1,050,342	February, ,, ..	1,219,701
November, ,, ..	1,089,023	March, ,, ..	1,220,000*
December, ,, ..	1,127,006		

* Approximate.

These figures do not include rate-aided patients in mental hospitals.

Local Government.

Lieut.-Colonel ACLAND-TROYTE asked the Minister of Health whether it was proposed to introduce legislation during the present session to give effect to the final report of the Royal Commission on Local Government.—Sir E. HILTON YOUNG replied: The final report of the Royal Commission contains recommendations on a large variety of subjects. Measures have already been taken to deal with some of them. I cannot undertake to propose further legislation this session on the recommendations.

Feeble-minded Persons in Britain.

Mr. LAMBERT asked the Minister of Health the estimated number of feeble-minded persons in Great Britain; and what proportion was cared for in public institutions.—Sir E. HILTON YOUNG replied: The number of mentally defective persons, including children, was estimated by the Wood Committee to be, approximately, 300,000. On Jan. 1st, 1932, the total number of mental actually ascertained by local authorities was 97,310, whom 33,356 were in institutions or under guardianship. These figures relate only to England and Wales.

Royal Commission on Sweepstakes and Lotteries

Mr. BERNAYS asked the Home Secretary whether he intended to institute an inquiry into the law relating to sweepstakes in this country.—Sir H. SAMUEL replied: It is generally agreed that there are serious difficulties in the way of enforcing the present law in regard to sweepstakes and lotteries. Events during the last two years have brought the matter very prominently to the attention both of the Government and the public. Questions have also arisen with regard to the use of totalisators both generally and in connexion with greyhound racing tracks. There are difficulties in connexion with the enforcement of the relating to street betting, and from time to time new developments arise such as the attempt to introduce betting at motor-cycle speedway races. In view of the complexity of the issues involved, and the diversity of the views entertained in regard to these questions, the Government have decided that, before considering whether any amendment of the present laws is necessary, it is essential that a comprehensive inquiry should be undertaken by a Royal Commission. Steps will accordingly be taken for the appointment of a Royal Commission, with wide terms of reference, as soon as the necessary arrangements can be made.

MONDAY, APRIL 11TH.

Child Marriage in India.

Mr. MCENTEE asked the Secretary of State for India the number of prosecutions taken out under the Sarda Child Marriage Restraint Act since its enforcement; and whether legislation was being placed before the Indian legislature providing for a limitation of the scope of the provisions of the Act.—Sir S. HOARE replied: I have no information regarding the number of prosecutions instituted under the Child Marriage Restraint Act. The Government have placed no legislation before the Indian Legislative Assembly with the object of limiting the scope of the Act, but a number of such Bills have been introduced by private Members.

Indian Medical Qualifications.

Lieut.-Colonel FREMANTLE asked the Secretary of State for India whether he had approved the Bill introduced into the legislative assembly for the establishment of a medical council in India and for the maintenance of a British-Indian medical register; whether he was assured that a standard of qualification would be made and maintained which would enable such qualification to be recognised by the General Medical Council of the United Kindom; and whether medical practice both in India and in the United Kingdom and other parts of the British Empire would be freely open to medical practitioners registered by either medical council.—Sir S. HOARE replied: The answer to the first part of the question is in the affirmative. There is, I think, good reason to hope that the standard of the Indian medical qualifications recognised by the Indian Medical Council will be such as will enable them to be recognised also by the General Medical Council here. As regards the last part the present Bill does not deal directly with the right to practise in India.

Lieut.-Colonel FREMANTLE asked if the right hon. gentleman had any assurance from the General Medical Council here that they would approve the standard set up by this Bill, in which case it would settle the question?

Sir S. HOARE replied that he had had no such assurance.

Lieut.-Colonel FREMANTLE: Is it possible to get some such assurance before this Bill is passed; otherwise Indian medical men qualified in India will be debarred from practising in different parts of the Empire?

Sir S. HOARE: I could not give an answer to that question without further consideration.

Lieut.-Colonel FREMANTLE: The right hon. gentleman says he has approved the Bill. Did he consider it before he gave his approval, or is it only a temporary, provisional approval?

[No reply was given to this question.]

Danger of Polluted Shell-fish.

Sir A. MICHAEL SAMUEL asked the Minister of Health what steps were taken by authorities other than the Fishmongers' Company to safeguard consumers against the dangers of imported polluted shell-fish other than oysters.—Mr. E. BROWN (Parliamentary Secretary to the Ministry of Health) replied: Sanitary authorities have general powers for the inspection and seizure of unwholesome food, and these are put into operation from time to time to prevent the sale of shell-fish which appear to be polluted.

Sir A. MICHAEL SAMUEL asked the Minister of Health what steps were taken to require that shell-fish imported from the Irish Free State should be cleansed and sterilised

Medical Diary

Information to be included in this column should reach us proper form on Tuesday, and cannot appear if it reaches later than the first post on Wednesday morning.

SOCIETIES.

YAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

Tuesday, April 19th.—5 P.M., Special Meeting of Fellows. To consider the proposed change in By-law 1, 7b. 5.30 P.M., General Meeting of Fellows. 8 P.M., Epidemiology and State Medicine. Disease in Children. Special discussion on Infection in the Dormitory. Openers: Dr. J. A. Glover and Dr. R. E. Smith, Epidemiology; Surgeon-Capt. S. F. Dudley and Dr. W. H. Bradley, Disease in Children. Other speakers will take part. Members of the Section of Medicine are specially invited to attend.

Thursday.—7.45 P.M., Neurology. A clinical meeting t the National Hospital, Queen-square, W.C. 8.30 P.M., Urology. Paper: Dr. Hugh Cabot (Mayo Clinic, Rochester, U.S.A.): Nephrostomy in Theory and Practice. Illustrated by diagrams and lantern slides.

Friday.—8 P.M., Epidemiology and State Medicine. Dr. A. S. M. Macgregor: Puerperal Fever and Pyrexia.

HELSEA CLINICAL SOCIETY.

Tuesday, April 19th.—8.30 P.M. (at the Hotel Rembrandt, Thurloe-place, S.W.), Wing-Commander H. A. Treadgold, R.A.F., will open a discussion on Physical Fitness and Aviation. The Meeting will be preceded by Dinner at 7.15 P.M. for 7.30 P.M.

OYAL MICROSCOPICAL SOCIETY.

Wednesday, April 20th.—5 P.M. (at B.M.A. House, Tavistock-square, W.C.), Discussion on the Microscopy of the Filtrable Viruses.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, April 18th, to Saturday, April 23rd.—Central London Throat, Nose, and Ear Hospital, Gray's Inn-road, W.C. Clinical Course in Diseases of the Ear, Nose, and Throat, occupying the whole of each day. Special (limited) classes in Operative Surgery, Pathology, Peroral Endoscopy.—London Lock Hospital, 91, Dean-street, W. Afternoon course in Venereal Disease. (The above courses are open only to Members.) Further particulars from the Fellowship of Medicine.

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith-road, W.6.

Monday, April 18th.—10 A.M. to 1 P.M., Gynæcological Ward, Surgical Wards. Genito-Urinary Operations, Skin Department. 2 to 4 P.M., Operations, Surgical Wards. Medical, Surgical, Gynæcological, and Eye Out-patients. 4.15 P.M. (Lecture), Mr. Sinclair: Acute Appendicitis.

Tuesday.—10 A.M. to 1 P.M., Medical Wards, Surgical Demonstration, Throat Operations, Dental Department. 2 to 4 P.M., Operations, Medical, Surgical, and Throat Out-patients. 4.15 P.M. (Lecture): Dr. Owen: Infant Feeding.

Wednesday.—10 A.M. to 1 P.M., Medical Wards, Children's Medical Out-patients. 2 to 4 P.M., Gynæcological Operations, Medical, Surgical, and Eye Out-patients. 4.45 P.M., Venereal Diseases Demonstration.

Thursday.—10 A.M. to 1 P.M., Neurological Out-patients, Fracture Demonstration. 2 to 4 P.M., Operations, Medical, Surgical, Genito-Urinary and Eye Out-patients. 4.15 P.M. (Lecture): Mr. Roche: The Investigation of a Urinary Case.

Friday.—10 A.M. to 1 P.M., Medical Wards, Skin Out-patients, Dental Department. 12 noon, Medical Lecture. 2 to 4 P.M., Operations, Medical, Surgical, and Throat Out-patients. 4.15 P.M. (Lecture): Dr. Owen: Infant Feeding.

Saturday.—9 A.M. to 1 P.M., Throat Operations, Medical and Surgical Wards, Surgical and Children's Medical Out-patients. The lectures at 4.15 P.M. on Mondays, Tuesdays, Thursdays, and Fridays are open to all medical practitioners without fee.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

Monday, April 18th.—8 P.M., Prof. J. C. Drummond: Recent Researches on the Nature and Function of Vitamins. (First of three lectures.)

ROYAL INSTITUTION, Albemarle-street, W.

Friday, April 22nd.—9 P.M., Prof. J. B. S. Haldane: Hereditary Transmission of Acquired Characters.

ST. PAUL'S HOSPITAL, Endell-street, W.C.

Wednesday, April 20th.—4.30 P.M., Mr. H. P Winsbury White: Diagnosis and Treatment of Surgical Diseases of Urinary Tract in Children.

ST. PETER'S HOSPITAL, Henrietta-street, Covent Garden, W.C.

Wednesday, April 20th.—3 P.M., Mr. R. O. Ward: Diagnosis and Treatment of Vesical Papillomata.

ST. MARK'S HOSPITAL, City-road, E.C.

Thursday, April 21st.—4.30 P.M., Mr. J. P. Lockhart-Mummery: Treatment and Prognosis; Cancer of the Rectum.

MANCHESTER ROYAL INFIRMARY.

Tuesday, April 19th.—4.15 P.M., Mr. A. H. Burgess: Back Pressure in Surgery.

Friday.—4.15 P.M., Dr. D. E. Core: Demonstration of Medical Cases.

SALFORD ROYAL HOSPITAL.

Thursday, April 21st.—Mr. L. D. Mercer: Demonstration of Aural Cases.

WESTERN INFIRMARY, Glasgow.

Wednesday, April 20th.—4.15 P.M., Dr. John Gracie: Medical Cases.

UNIVERSITY OF BIRMINGHAM.

Wednesday, April 20th.—4 P.M., Mr. C. J. Bond: Some Aspects of Human Biology. (First of five William Withering memorial lectures.)

Vacancies

For further information refer to the advertisement columns.

Altrincham General Hospital.—Jun. H.S. At rate of £120.

Barrow-in-Furness, North Lonsdale Hospital.—H.S. £175.

Barry [illegible] 200.

Beckenh[illegible] *Orchard, Eden Park.* Res[illegible]

Birmingham, Dudley-road Hospital.—Jun. Asst. Res. M.O.'s. At rate of £200.

Blackburn Royal Infirmary.—Res. H.P. £175.

Brighton. Royal Sussex County Hospital.—H.P. £150.

Burton-on-Trent, General Infirmary.—Cas. O. and H.P. £150.

Canterbury, Kent and Canterbury Hospital.—H.P. At rate of £125.

Charing Cross Hospital, W.C.—Res. Cas. O. £200.

Chester, East Lancashire Tuberculosis Colony, Barrowmore Hall, Gt. Barrow.—H.P. At rate of £100.

Cobham, Surrey, Schiff Home for Recovery.—Res. Surgeon. At rate of £200.

Colchester, Essex County Hospital.—Asst. H.S. £120.

Derby, Derbyshire Hospital for Sick Children.—Res. H.S. At rate of £130.

Durham County Hospital.—Two H.S.'s. Each £150.

Ealing Borough.—Asst. M.O.H. £600.

Elizabeth Garrett Anderson Hospital, 144, Euston-road, N.W.—Pathologist. £300.

Evelina Hospital for Sick Children, Southwark, S.E.—Hon. Phys. to Out-patients.

Folkestone Borough.—Asst. M.O.H. £600.

Hampstead General and North-West London Hospital, Haverstock-hill, N.W.—H.S. £100.

Hastings, Royal East Sussex Hospital.—Sen. H.S. At rate of £150.

Hospital for Sick Children, Great Ormond-street, W.C.—Secretary. £750.

Hull Royal Infirmary.—H.P. for Sutton Branch Hospital. At rate of £160.

Ilford, King George Hospital.—Two H.S.'s. Each at rate of £100.

Ipswich, East Suffolk and Ipswich Hospital.—H.S. £120.

Isleworth, West Middlesex County Hospital.—Ophthalmic Surgeon. 3 gns, per session.

Leeds Hospital for Women.—H.S. At rate of £100.

Leeds Maternity Hospital, Hyde-terrace.—Sen. H.S. and Jun. H.S. At rate of £52 and £26 respectively.

London Light and Electrical Clinic, Ranelagh-road, S.W.—Hon. Manipulative and Electrical Clinic.

London University.—University Chair of Physiology. £1100.

Manchester, Royal Children's Hospital, Pendlebury.—Res. M.O. At rate of £125.

Minehead, Somerset, Minehead and West Somerset Hospital.—Res. M.O. At rate of £150.

National Temperance Hospital, Hampstead-road, N.W.—Hon. Asst. Phys.

Newcastle-upon-Tyne Hospital for Sick Children.—H.P., Sen. H.S., and Jun. H.S. Each at rate of £100.

Newcastle-on-Tyne, Royal Victoria Infirmary.—Jun. Surg. Reg. £150.

Northampton General Hospital.—H.S. to Ear, Nose and Throat Department. At rate of £150.

Portsmouth. Royal Hospital.—Cas. O. At rate of £100.

Preston and County of Lancaster Royal Infirmary.—Cas. O. At rate of £150.

Queen's Hospital for Children, Hackney-road, E.—Clin. Asst. for Med. Out-patients. 5s. each attendance.

Radcliffe-on-Trent, Notts, County Mental Hospital.—Second Asst. M.O. £450.

[illegible].—H.P., Cas. O., and Res. M.O.

[illegible] *stitution.*—Fourth M.O. £400.

[illegible] *ay, N.*—H.P. At rate of £70.

[illegible] *.E.*—Cas. O. At rate of £100.

[illegible], *Rotherhithe, S.E.*—Res. H.P. At rate of £80.

St. Thomas's Hospital, London, S.E.—Chief Asst. to Ophth. Dept.

South London Hospital for Women, Clapham Common, S.W.—H.S. At rate of £100.

University College, Gower-street, W.C.—Bayliss-Starling Memorial Scholarship. £120.

Walsall General Hospital.—Res. Surg. O. At rate of £300.

Wealdstone Parish,—District M.O. £100 Also Public Vaccinator.

Wrexham and East Denbighshire War Memorial Hospital.—Res. H.S. At rate of £150.

York, North Riding Mental Hospital.—Temporary M.O. 7 gns. per week.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at St. Just (Cornwall); Easingwold (Yorks, North Riding); Hornsea (Yorks, East Riding); Sutton-in-Ashfield (Notts); and Haslemere (Surrey).

MEDICAL NEWS

University of Oxford.

The George Herbert Hunt travelling scholarship for 1932 has been awarded to John Charles Leedham-Green, B.M.

Next June there will be an election to the Schorstein Research Fellowship in Medical Science. The Fellowship, of the annual value of £200, will be tenable for two years from Oct. 1st in any of the medical departments at Oxford. Candidates must be graduate members of the University, holding a registrable medical qualification, and must be under 35 years of age on Oct. 1st. They must submit their applications, in proper form, to the Dean of the Medical School, University Museum, not later than May 2nd.

University of London.

At University College Dr. C. S. Myers, F.R.S., will deliver the Hobhouse memorial lecture on the Absurdity of any Mind-Body Relation, at 5.30 P.M. on Thursday, May 19th. Three lectures on Human and Comparative Placentation, including the Early Stages of Human Development, will be given by Dr. Otto Grosser, professor of anatomy in the German University, Prague, at 5.15 P.M. on May 2nd, 5th, and 6th. Dr. W. R. Hess, professor of physiology in the University of Zurich, will deliver two lectures on the Autonomic Nervous System at 5.30 P.M. on May 12th and 13th.

The Senate will shortly consider applications for grants from the Thomas Smythe Hughes and Beaverbrook Medical Research Funds for the assistance of original medical research. Applications must be received in proper form not later than May 15th. Applications are also invited for the Laura de Saliceto studentship for the advancement of cancer research, which is of the value of £150 a year. Further particulars of the grants and studentship may be had from the Academic Registrar.

Our advertisement columns contain particulars of the Geoffrey Duveen travelling studentship for research in oto-rhino-laryngology, for which application is invited.

University of Birmingham.

The Ingleby lectures will be given in the Edmund-street Buildings at 4 P.M. on Thursdays, May 5th and 12th, by Prof. Seymour Barling, whose subject will be the Operative Treatment of Toxic Goitre. As already announced, the Withering lectures, on Some Aspects of Human Biology, will be given by Mr. C. J. Bond, at the same hour and place, on Wednesdays, April 20th and 27th, and May 4th, 11th, and 25th.

Hunterian Society.

The next award of the Society's gold medal will be made in 1932 for the best essay received on or before Dec. 31st. The competition is open to all general practitioners resident in Great Britain, Ireland, and the Channel Islands, and for this purpose the council define a general practitioner as one who is not established in a special branch of work or in consulting practice. The rules governing the award may be obtained from the secretary, Mr. Andrew McAllister, 79, Wimpole-street, W.1.

More Money than Patients.

Prudhoe Memorial Convalescent Home, Whitley Bay, Northumberland, has a credit balance of £936 but lacks a sufficiency of inmates, the number, entirely men, having fallen by 150 to 1007. The reasons given are the straitened resources of employers, workmen's societies and clubs, and the opening of the home at Conishead Priory for miners in the county of Durham. A subscriber of £2 2*s.* is entitled to send a convalescent for three weeks although the cost to the Home is £4 10*s.* 2*d.*

National Birth Control Association.

This association, with which is incorporated the Birth Control Investigation Committee, will hold a medical conference at the Caxton Hall, London, from May 20th to 22nd. The subject of the meetings and the names of the chairmen are as follows: Friday, May 20th, 2.30 P.M., Spermotoxins and Hormones (Sir Thomas Horder); May 21st, 10.30 A.M., Spermicidal Preparations and their Effects (Dr. C. P. Blacker); May 21st, 2.30 P.M., Methods at Present in use at Clinics (Dr. Killick Millard); May 22nd, 10.30 A.M., the Gräfenberg Ring and other Methods (Sir Humphry Rolleston). It is stated that the members of the conference will be medical officers of health and members of their staffs, research workers, doctors in hospitals and in private practice, and doctors and a few lay workers from the voluntary clinics. Particulars may be had from the secretary of the association at 25, Eccleston-street, London, S.W.1.

Royal Faculty of Physicians and Surgeons of Glasgow.

Sir D'Arcy Power will deliver the Finlayson memorial lecture in the Hall of the Faculty, 212, St. Vincent-street, Glasgow, at 4 P.M., on Thursday, April 21st. His subject will be the Progress of Surgery in a London Hospital 1880–1930, and all medical practitioners are invited to attend.

Indian Medical Service Dinner.

The annual dinner of the Indian Medical Service will be held at the Trocadero Restaurant, London, on Wednesday, June 15th, at 7.15 P.M. Major-General J. W. D. Megaw has been invited to take the chair. Tickets and all particulars may be had from the joint honorary secretary, Major Sir Thomas Carey Evans, Hammersmith Hospital, Ducane-road, London, W. 12.

Post-graduate Course for Ship Surgeons.

The first part of a course for ship surgeons has just begun in London under the auspices of the Seamen's Hospital Society, Greenwich. Further sections of the course will be held in the summer and autumn.

Post-graduate Course in Tuberculosis.

Under the auspices of the tuberculosis department of the Welsh National School of Medicine, and the Welsh National Memorial Association, a week's post-graduate course in tuberculosis will be held in Cardiff from June 1st. The provisional programme may be had from the hon. secretary for post-graduate courses, Joint Tuberculosis Council, 8, Highway-court, Beaconsfield, Bucks.

New Tuberculosis Clinic in Manchester.

On April 4th the Lord Mayor opened the new tuberculosis dispensary, or clinic, as it is to be called in future, which the Manchester public health committee has built opposite the Royal Infirmary. It will be the administrative centre of the tuberculosis scheme. The building has cost £22,000.

John Abernethy in a Broadcast Play.

A play about Dr. John Abernethy, written by Mr. Rudolph de Cordova and his wife, Miss Alicia Ramsey, is to be the first play broadcasted from the new Broadcasting House in London on May 2nd and 3rd. It was given over the wireless four times last year.

Torbay Hospital.

Last year this hospital admitted 2097 patients, as against 1941 in 1930 and 1668 in 1929; their average weekly cost was £2 18*s.* 4*d.*, and their average stay 22·4 days. Of the total ordinary income of £20,000 the contributory scheme provided £5685.

Anglo-Yugoslav Hospital, Belgrade.

Dr. Katherine Macphail, founder and medical superintendent of this hospital, states that children are being turned away nearly every day owing to lack of accommodation. This is one of the consequences of the closing of 20 out of the 50 beds owing to the reduction of support given by English friends of Serbia through the Save the Children Fund, which makes a special appeal for funds to maintain the work. Gifts may be sent to Mr. H. D. Watson, chairman and hon. treasurer, 40, Gordon-square, London, W.C.1.

Royal Microscopical Society.

At a meeting of this society to be held at the B.M.A. House, Tavistock-square, London W.C., at 4 for 5 P.M., on Wednesday, April 20th, Mr. Conrad Beck, the president, will open a discussion on the Microscopy of the Filtrable Viruses. He will be followed in the discussion by Mr. J. E. Barnard, F.R.S., Prof. J. C. G. Ledingham, F.R.S., Dr. S. P. Bedson, Mr. C. C. Hurst, Prof. J. McIntosh, Capt. S. R. Douglas, F.R.S., Mr. W. J. Elford, Dr. G. M. Findlay, Mr. B. K. Johnson, and others.

Hospital Visiting Days.

It is proposed to limit the visiting of patients in the Manchester municipal hospitals to three afternoons a week, and to issue only three visiting permits to the relations or friends of each patient. Hitherto visits could be paid every afternoon, and visiting has grown to such an extent as to interfere with the work of the wards. It is found that so many and such frequent visitors disturb the patients, retard their recovery by the discussion of "home worries," hinder the training of nurses, and make the wards dirty, while visitors are often persons whom the patients do not wish to see. On a recent afternoon 1300 visitors entered an institution in 70 minutes while on a Saturday the number exceeded 1800.

nonite, ⅓ inch across. not found in Liberia. and ad had it identified by Prof. Degner in Hamburg by Major M. Connolly in London. The town is. tells us, near the top of a hill, and below in the ey is a rice farm. On the way to this is an area d as the general latrine. lying at the head of a ll brook which carries fæces. &c.. to the stream ow. This brook enters at the top of a half-mile ch, which he found had been selected by reason ts nearness, its open access and sunlight. and its tle current. for the watering, washing, and bath- activities of the village women and children. e same physical advantages. and the fæcal con- nination. make the reach also a favourite for ter-snails. In a couple of hours Vogel got 517 *ysopsis globosa* and 178 *Planorbis pfeifferi* from reach; the physopsis had no *mansoni* cercariæ, t the planorbis had; and planorbis. kept a time quarantine to prove they were uninfected, were edily attacked by miracidia from a monkey ected by *S. mansoni*, with resulting sporocyst mation. The monkeys had been infected either ally or through the skin, and their fæces, tested by e Teleman method, showed *S. mansoni* ova 40–50 days, while male and female worms were nd post mortem in the portal and other veins. gel recommended that a new channel be dug the stream to sidetrack "the reach" and l its snails by drying, and that new watering- aces be made free from planorbis. Bridges or ank roads over swamps would reduce infections. says. but better arrangements for latrines are ost chiefly needed. Specific mass treatment of tives will, he thinks. do little good until these her measures are in train.

ANIMALS IN CAPTIVITY.

THE opening of the zoological park at Whipsnade st May has given the Zoological Society of London magnificent opportunity of showing what can be one to maintain the health of wild animals in aptivity. Last summer was not all that it should ave been and the winter has had severely cold spells, ut the majority of the animals at Whipsnade have hrived in all weathers. Two pigmy hippopotamuses om tropical West Africa, which spent several weeks n one of the large paddocks with no artificial heat, ut on weight and grew hair on their bodies. An lephant also grew abundant hair on its back. A umber of animals at Whipsnade have signified their esponse to the healthy life by breeding. among them aks, llamas. red and fallow deer. wallabies, muntjacs. nd even wolves. The policy at Whipsnade has been o allow all the animals the greatest possible amount of space and liberty, with the result that the public as made some complaint that few animals are to e seen. This is now being rectified partly by the nimals already there becoming so tame as to be asily visible, partly by the steady development of accommodation for others; there is already one den for lions in a reinforced chalk quarry, and a large enclosure of rough scrub is being fenced in to serve as a second den. Colonies of European and Canadian beavers have been introduced into three small permanent ponds, and some February swamps are being made permanent by puddling the flooded ground. Barley left standing on five acres affords cover for pheasants, partridges. and ground game, while the foxes which it was deemed prudent to evict when the park was enclosed are apt to return and make depredations on more peaceable inmates. Grey squirrels and rats have been destroyed. and numberless rabbits are transferred to the larder of the London gardens.

The health record at Regent's Park also is increasingly good. Last year only one monkey died of tubercle, and it was probably already infected on arrival. A kangaroo which died of tubercle in the pancreas was found by Dr. Stanley Griffith to harbour the avian type of bacillus. Enteritis, regarded as a good indication of the standard of cleanliness and general sanitation. falls steadily from year to year. Cat distemper only affected three recently imported leopard cubs. an immunity no doubt due in part to the provision of a new isolation ward. Rickets in young monkeys is being treated with increasing success with cod-liver oil and sun rays, but evidence is growing to show that the disease in civets and genets is not of the same character, and does not yield to the usual antirachitic treatment. Only one cancerous growth was found during the year—namely, a kidney tumour in a hamster. Kidney disease with dropsy is not an uncommon cause of death in elderly carnivores. Respiratory diseases being primarily climatic are found more difficult to control, and remain fairly constant; but speaking generally, the period required for acclimatisation has been steadily reduced. Finally, we should not overlook the service rendered to the eyes of sundry beasts by Miss Ida Mann, who removed a senile cataract from a Capuchin monkey, and needled the lens capsule of a young lemur with congenital cataract. with recovery of sight in each case. Altogether the zoo. old and new, affords the visiting public many useful lessons by analogy in adaptation to environment.

THE LADY CHICHESTER HOSPITAL.

THIS hospital at Hove, which is designed to receive cases of early nervous breakdown, had 45 patients in residence at the end of 1930, while its out-patient department saw 1778 patients during the year. Increasing demands upon the hospital have necessitated further extension, and a new department for men has been opened in coöperation with the Royal Sussex Hospital. There are now eight beds for men, 47 for women, and six for children. The financial position of the hospital causes great anxiety, but the demand for treatment is always greater than the available supply. Patients are put to bed at first and given plenty of rest, good food. fresh air, and sunlight. Occupational therapy, both in organised forms and by means of amusements and hobbies generally, forms a very important part of the treatment. Toxic foci are sought and eliminated, and hydrotherapy, massage, and electrical treatment are found valuable. A useful development has been the establishment of a system of "daily out-patients"—patients who spend their day at the hospital, but sleep out. The hospital has its own magazine, written, illustrated, and typed by the patients. Ex-patients are followed up and for those who live in the locality there is a weekly "club night" of entertainment, dancing, or lecture.

HYPERPYREXIAL HEAT-STROKE.

NOT long ago we commented on a number of papers on heat-stroke.[1] In their wake comes one from Australia. on Hyperpyrexial Heat-stroke, by K. G. Hearne.[2] This gives an excellent account of the climatic conditions which our troops had to contend with in Mesopotamia during the late war. The abnormal heat-wave—abnormal even for Mesopotamia—experienced in July, 1917, when for 18 consecutive days the maximum shade temperature averaged 119° F., provided a crop of hyperpyrexial cases which gave Dr. Hearne a valuable opportunity for clinical study. His experiences are recorded in detail, and while little fresh knowledge comes to light, much that has previously been conjectured receives ample confirmation. The chief interest of his paper lies in the success obtained in aborting threatened attacks. It is well proved that if suppression of sweating and frequency of micturition occurs, the sufferer should at once repair to the nearest sick-quarters for treatment. Dr. Hearne's experiences with hyperpyrexial attacks in troopships, and his deductions which rule out phlebotomus fever and malaria as primary causes of the condition, are decidedly helpful. It is perhaps a pity, however, that no mention is made of the presence or absence

NOTES, COMMENTS, AND ABSTRACTS

THE CIGARETTE HABIT.

AT a meeting of the Society for the Study of Inebriety on April 12th, with Lady BARRETT, the President, in the chair, Dr. J. D. ROLLESTON surveyed published reports on the effects of cigarette smoking. Cigarettes, he said, had not been smoked in England to any large extent until after the Crimean war, and women had not adopted the habit until late in the last century when ladies of the demi-monde had first taken to smoking. The habit had increased considerably at the time of the late European war, and it had been estimated that in America $922,500,000 was spent annually on cigarettes—a sum sufficient to build two and a half Panama canals. The percentage of nicotine in cigarette smoke was about half that in cigar or pipe smoke, but it contained a relatively large proportion of carbon monoxide, which was capable of producing the symptoms of mild carbon monoxide poisoning in persons who smoked more than 20 cigarettes a day. Cigarettes also contained traces of pyridine and furfural.

The process of cigarette smoking was rhythmical, soothing, and pleasant, but it was unquestionably a drug habit. There was no evidence in support of the popular view that cigarette smoke was antiseptic, and decay of teeth might progress in the mouths of heavy smokers. The habit reduced appetite and affected health, and was, in the view of some observers, one of the factors responsible for the increase of tuberculosis in young girls. There was also evidence to show that it was often associated with gastric or duodenal ulcer. The effect of cigarette smoking on the respiratory system was a local irritation affecting the pharynx, larynx, and trachea. Hildebrand attributed to the habit chronic bronchitis, spasm of the bronchi with bronchial asthma, and relaxation of the muscles of the bronchi. These results were quite likely to develop in nonsmokers who were constantly in a smoky atmosphere. The effects of excessive smoking on the cardiovascular system were increase in the pulse-rate, palpitation, arrhythmia, rise of blood pressure, and cardiac neuroses, with occasional development of the symptoms of angina pectoris. Few observations on the blood of heavy smokers had been recorded, but one case had been reported of a leech which, after tasting the blood of such a patient, had fallen off and died in convulsions. Nervous symptoms included tremor, giddiness, headache, and insomnia. Conjunctivitis sometimes occurred, but amblyopia was rare in cigarette smokers. The relation between cigarette smoking and cancer was debatable; it was thought by some to play the part of a chronic irritant in the production of leucoplakia of the lips and tongue. Cancer of the lung was increasing in incidence and was said to be relatively frequent in waiters and innkeepers who worked in a smoky atmosphere. Opinion was fairly unanimous that smoking was deleterious to young persons, and in America some attempt had been made to demonstrate a connexion between delinquency in children and cigarette smoking. He quoted the opinion of two observers that the allowance for an adult should be five cigarettes a day.

Sir ROBERT ARMSTRONG-JONES mentioned the case of some boys admitted to Claybury with mental symptoms following on the anæmia induced by excessive smoking. Smoking induced a passive, suggestible state in which images might be regarded as realities. On the other hand, cigarette smoking might act as an antidote to a disturbed mental state, and the London County Council had recently decided to spend a large sum yearly on tobacco for use in their lunatic asylums. He agreed that it was better that young or highly strung persons should not be allowed to smoke.

Dr. A. P. CAWADIAS pointed out that as the smokers far outnumbered the non-smokers, there must always be a preponderance of smokers among a group patients suffering from any disease. Tobacco smokin however, certainly had the effect of raising the bloo cholesterol, and in some patients this tended t produce changes in the arterial walls and endarterit obliterans. In another group of patients tobacc acted on the sympathetic nervous system and gav rise to gastro-intestinal symptoms. Cigarette smokin might be valuable in some cases, soothing the nervou system; in others it was deleterious.

Mr. W. MCADAM ECCLES pointed out that intermittent claudication was rare except in Polish Jew and that cigarette smoking was widespread, so tha some individual factor was probably operative i this condition. Gastric ulcer had at one time bee common in young women, owing, he considered, t septic teeth. Nowadays it was less common in youn women and much commoner in young men; h believed that cigarette smoking was partly responsib for the increase, coupled with the fact that youn women took more care of their teeth than youn men.

Dr. W. M. FELDMAN described a case of suspecte pyloric stenosis in an infant whose mother was heavy smoker. No signs of pyloric stenosis wer found on examination, and he suspected nicoti poisoning; anlaysis of the mother's milk, howeve revealed not a trace of nicotine. He suggested th the cigarette habit and delinquency in children mig both spring from some common cause instead standing in the relation of cause and effect.

Prof. LEONARD FINDLAY asked why the increase cigarette smoking in women should be associate in them, with a reduction in the incidence of gast ulcer. He thought the worst harm attributable cigarette smoking was an irritation of the upper passages, and he was not astonished that it shou be deleterious to tuberculous patients for th reason.

THE PREVENTION OF SCHISTOSOMIASIS.

SCHISTOSOMA infection, widespread in the tropi is of two sorts, due to *S. hæmatobium*, which attac mainly the genito-urinary system, or to *S. manso* which attacks the rectum. The ova in water devel miracidia, which in suitable water-snails ency themselves and give rise to free-swimming cercari These perforate the skin of people who wade or wa in water, or the intestinal mucosa of people w swallow them in drinking; and in the human bo they achieve their sexual stage. Prevention, ap from general hygiene, is by destruction of the wat snails particularly involved. These intermedi hosts are not yet in all areas certainly identifi and to their discovery in Liberia and French Guin Dr. Hans Vogel,[1] of the Hamburg Tropical Medici School, has devoted much skill and energy. Worki at the Bolahun Missionary Hospital in the north Liberia in the rainy season (April to September) 1930 he found that some 40 per cent. of the nati were infected with *S. hæmatobium*, and that t intermediate host was unknown. *Physopsis globos* believed to be the carrier in neighbouring Sierra Leo but no cercariæ came from the physopsis examin in Liberia, nor would miracidia attack physop there (480 snails examined). As to *S. mansoni*, wh causes infection in Liberia but rarely, the cases se are mostly in immigrants. Dr. Vogel made two tr to the near-by French native town, Tamassodou, wh *S. mansoni* infection was rife. He had difficulty obtaining fæces for examination, but children, temp by ices, would coöperate. Of 81 persons examin 75 (over 90 per cent.) were infected, and this gr difference was explained when, almost at once, he fou a water-snail, new to the area, *Planorbis pfeiff* which carried *S. mansoni*, a small shell like

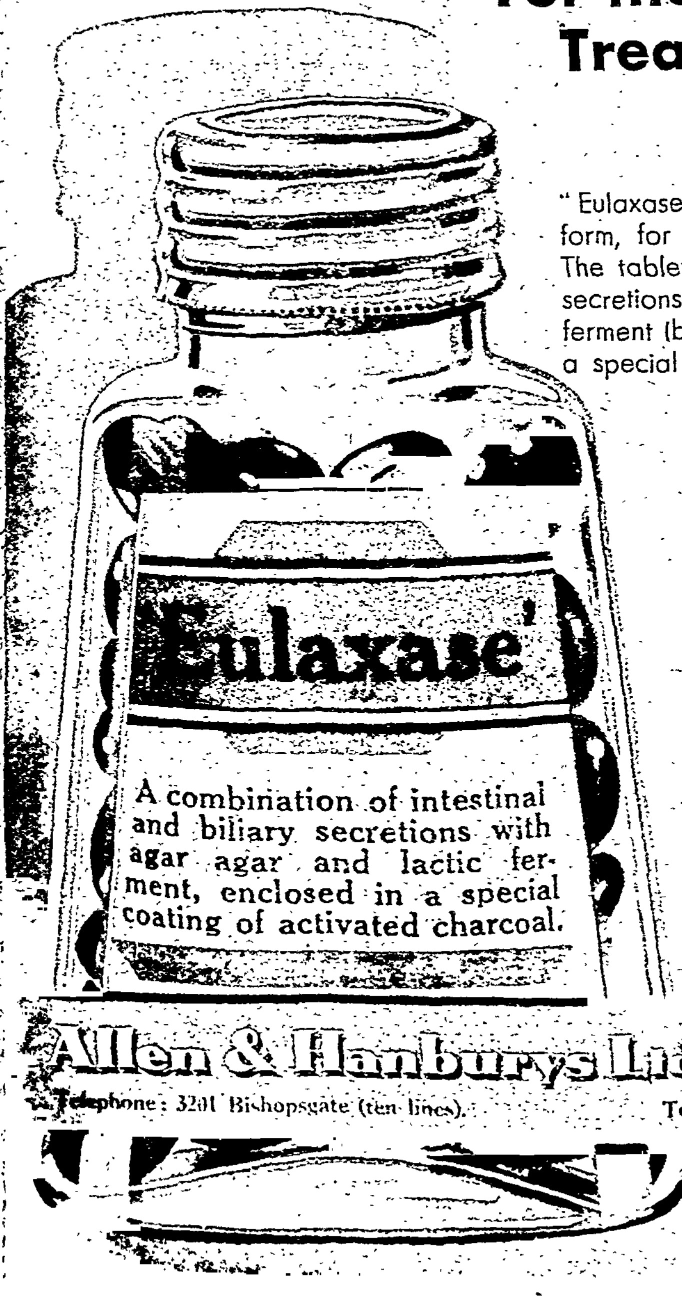
Prescribe British

"EULAXASE"

For the Rational Treatment of Constipation



Eulaxase
A combination of intestinal and biliary secretions with agar agar and lactic ferment, enclosed in a special coating of activated charcoal.

"Eulaxase" is a new preparation, in tablet form, for the treatment of constipation. The tablets contain biliary and intestinal secretions, with agar-agar and lactic ferment (bacillus acidophilus), enclosed in a special coating of activated charcoal.

The essential advantage of "Eulaxase" is that it provides a special substitute for each of the chief factors that are deficient in intestinal stasis. In other words, it forms a natural, complete, and efficient means of treatment for constipation.

In bottles of 60 tablets for prescribing, and 600 tablets for dispensing.

Descriptive leaflet and clinical trial sample will be sent on application.

Allen & Hanburys Ltd., London, E.2

Telephone: 3201 Bishopsgate (ten lines). Telegrams: "Greenburys Beth London."

In bottles containing 60 tablets 2/6

[*See also pp.* 12, 26, & 27]

of indicanuria in his cases, for the discovery of indican would support the auto-intoxication theory which he dismisses as unlikely without confirmation. While it may be agreed that sweat suppression is a primary cause of heat hyperpyrexia, it is still quite probable that auto-intoxication plays a part.

CENTENARY OF C. J. HEWLETT AND SON, LTD.

WE have received a history of the house of C. J. Hewlett and Son, Ltd., put together from reports which have appeared in the pharmaceutical and scientific press, the occasion of the publication being the celebration this year of the centenary of the business. We have personal reasons for liking to think that the existence of a business for one hundred years is a proof not only of continuity but of progress.

The founder of the business, Mr. C. J. Hewlett, gained his knowledge of pharmacy by driving over England in a horse and gig as a commercial traveller for the now extinct firm of Tosswills. Between 1832 and 1870 he was associated with several partners in a business which was growing up on general lines, and in the latter year he was joined by his son, Mr. John Hewlett. The son struck out a special line by producing a number of high-grade non-secret pharmaceutical preparations, and establishing a large trade in them overseas. The founder of the firm died at the beginning of this century at the age of 90, and shortly afterwards the business was turned into a limited company, among the directors being his son, Mr. John Hewlett, his grandson, Mr. Vivian Hewlett, and Mr. J. D. Allman, the senior representative of the firm in the home markets. During the war the firm did excellent service in supplying drugs to hospitals, doctors, and pharmacists at home and abroad. Shortly afterwards Mr. John Hewlett, died, and was succeeded as chairman by his son, Mr. Vivian Hewlett, Mr. E. J. Millard being associated with him as managing director. Under their activities the firm has made great developments, material evidence of which is supplied by the extension of premises and the establishment, under Mr. Norman Millard, of an excellent analytical laboratory.

A centenary dinner will be held on Saturday April 23rd, at the Abercorn Rooms, Bishopsgate, E.C

ACID-BASE EQUILIBRIUM IN SKIN DISEASE

G. Milian and L. Brodier,[1] in a review of dermatological topics, quote some recent observations by Spillmann and Verain. Taking —7·35 as the normal pH, and using an electrometric method of determination, these workers find a definite acid-base disturbance in the blood of people suffering from eczema, eczematides, urticaria, prurigo, psoriasis, and dermatitis herpetiforme. They believe that this loss of equilibrium plays an important part in exudative affections, and eczema in particular. Twenty-two per cent. of the cases tended to the acid side, and 73 per cent. to the alkaline; there was considerable difference in the amount of variation from case to case, and apparently no relation to the severity of the clinical manifestations. It is of some value to note that in their experience a return towards normal in the acid-base balance is of good prognostic import, while persistence of the disturbance indicates the probability of a relapse. From the therapeutic point of view it is easier to rectify the acid tendency with sodium bicarbonate than to alter the alkaline tendency by means of phosphoric acid, calcium chloride in large doses, or autohæmotherapy. There is neither an "acid" nor an "alkaline" dermatosis. It is the loss of balance between the two which is of pathogenic importance, and often this is itself only a sign or effect of another disturbance, endocrine or vago-sympathetic. It follows that in the effort to counteract the ascertainable loss of acid-base balance, the physician must not shut his eyes to the possibilities of more fundamental factors.

TOURS IN RUSSIA.

As announced in a letter in our issue of March 26th, the Society for Cultural Relations with the U.S has arranged three tours in Russia, leaving L on July 16th, August 13th, and Sept. 10th. these dates cut across those of the British Me Association's centenary meeting in London (from July 21st) and the Physiological Society's meeting in Rome (August 29th), it has been decided to arrange an earlier tour if enough applications are received before May 20th.

The party would leave London on June 18th for a tour of Leningrad, Moscow, Nijni-Novgorod, and down the Volga to Stalingrad, returning to London by boat, and arriving on, or about, July 12th. The charge would be not more than £35 (inclusive of return fares, hotels, tips, food, theatres, and interpreters). Further particulars may be had from the secretary of the Society, 1, Montague-street, London

MYASTHENIA GRAVIS.

"INQUIRER" writes: I would be very grateful to learn from any reader where to obtain some recent information concerning the ætiology and treatment of myasthenia gravis. The patient is a doctor.

Appointments

EDBROOKE, F. R., M.B., Ch.B. Brist., D.P.H., has been appointed Medical Officer of Health, Coulsdon, Purley, Beddington and Wallington Councils.

HOWIE, L. J., M.B., Ch.B. Edin., Asst. Medical Officer of Health and Asst. Tuberculosis Officer, Midlothian, West Lothian and Peebles.

MCGARRITY, J., M.D. Edin., D.P.H., Medical Superintendent of the City Hospital, Little Bromwich, Birmingham.

TOPPING, M. D., Ch.B. Aberd., D.P.H., Medical Superintendent in the L.C.C. Public Health Dept.

Certifying Surgeons under the Factory and Workshop Acts: BRIGG, D. A., M.B., B.S. Lond. (Chipping Norton); CROSS, R. M. S., L.R.C.P. Lond., M.R.C.S. (Petersfield); and HAIR, A., L.R.C.P. Lond., M.R.C.S., D.P.H. (Presteign Radnor).

Births, Marriages, and Deaths

BIRTHS.

HOWELL.—On April 7th, the wife of Dr. J. Bonnell Howell, Brook Green, W., of a daughter.

SMYTH.—On April 10th, at Wimpole-street, W., the wife of Michael Smyth, F.R.C.S., of a son.

MARRIAGES.

BIGBY—NEW.—On April 9th, at Southwark Cathedral, Dr. William Louis Murray Bigby to Hilda Marian, younger daughter of the late Mr. and Mrs. G. H. New, of Cheltenham.

HAMILL—FINDLATER.—On April 7th, at Our Lady of Victories, Kensington, John Molyneux Hamill, O.B.E., M.D., D.Sc., to Lesley, daughter of the late R. B. N. Findlater and Mrs. Findlater, of Queen's-gate, S.W.

DEATHS.

APPLETON.—On April 6th, at Canford Cliffs, Bournemouth, James Enderby Appleton, M.R.C.S., L.D.S. Eng., of Penticton, British Columbia, late of "Linda," Poole-road, Bournemouth.

[illegible] 10th, at Burntwood-lane, Wandsworth, [illegible] M.R.C.S., L.R.C.P., L.D.S., late of [illegible] Hyde Park, and North Walsham.

[illegible] d, Richard Lawson, M.R.C.S., L.R.C.P., late of Balham Hill.

WADDY.—On April 8th, Henry Edward Waddy, M.R.C.S., L.R.C.P. D.P.H. Camb., of Rhossili, Brunswick-road, Gloucester.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

VICTORIA PARK HOSPITAL.—It was reported at the annual meeting last week of the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, E., that trade depression has reduced annual subscriptions and patients' contributions, while payments by county authorities in respect of treatment of their patients have also fallen off to a great extent because these bodies are increasingly building their own hospitals and sanatoriums.

ADDRESSES AND ORIGINAL ARTICLES

THE RÔLE OF THE HÆMOLYTIC STREPTOCOCCI IN INFECTIVE DISEASE.

C. C. OKELL, M.C., M.B. CAMB., M.R.C.P. LOND.,
PROFESSOR OF BACTERIOLOGY IN THE UNIVERSITY OF LONDON, AND BACTERIOLOGIST TO UNIVERSITY COLLEGE HOSPITAL, LONDON.

LECTURE III.

CLINICAL AND EPIDEMIOLOGICAL INTER-RELATIONSHIPS IN STREPTOCOCCAL DISEASE.*

IN my previous lectures I have discussed some of e more general features of pathogenic effects due the hæmolytic streptococci and have tried to tablish the view that a large number of streptococci om the most diverse sources in human disease ave apparently the same weapons of attack, a rogenic property and an erythrogenic toxin. That hile one or other of these weapons may be predominntly evident in a given human disease, under perimental conditions potentialities in both direcons are very general, if not universal, among the emolytic streptococci.

"If anything is established," said Cohnheim, it is what may be called the distinct individuality f the different infectious diseases," but in recent ears we have come to recognise that certain balances etween host and parasite may produce very dissimilar clinical entities though the species of parasite nd host remain the same. Thus herpes and chickenox are both diseases with distinct "individualities" hough we may see the same virus producing the wo diseases in *different individuals.* It is not ne of the least striking things about streptococcal disease that bacteria so similar in form and experimental properties should give rise to so many and well-defined clinical and epidemiological types of disease. Since the earliest days of streptococcal esearch two views have been held as to the relationhip of the streptococci to disease. The first is hat each well-defined clinical entity is associated with a special kind of streptococcus. This, the "specificity" view, is expressed in the use of such terms as *S. scarlatinæ*, *S. erysipelatis*, *S. pyogenes*, &c., as specific names for the streptococci associated with the different diseases. The second view is that different diseases due to the hæmolytic streptococci are due essentially to one species of streptococcus. According to this view, factors of varying virulence and toxicity on one side and varying susceptibility on the other are held to account for the different streptococcal diseases outwardly so unlike. This is what I have called the "unitarian" view. I cannot here follow the varying fortunes of these two rival theories, though the history in itself is full of interest. It is perhaps sufficient to say that before the publications of the Dicks and Dochez in 1924, a more or less unitarian view held sway and was expressed by such workers as Marmorek,[1] Neufeld,[2] and Aronson.[3]

The far-reaching influence of Jochmann's[4] view, that scarlet fever was not due to streptococcal infection allowed the problem of scarlet fever to be shelved and therefore one of the outstanding difficulties in accepting the unitarian view was avoided.

The work of the Dicks and Dochez, though it only put on a more solid footing the views held many years previously by Moser, Gabritschevsky and Savchenko on the toxigenicity of scarlet fever streptococci. at once led nearly all observers to focus on the specificity view because at first sight it was thought that only such a view would be in accord with the peculiar immunological properties of the erythrogenic toxin they described. A further encouragement to the specificity view was given by the work of Birkhaug on erysipelas. This observer came to the conclusion that the pathogenic effects of hæmolytic streptococci from cases of erysipelas had specific characters; he also studied a toxin resembling that obtained from scarlatinal strains, but he considered it to be immunologically distinct. I may mention that my colleagues and I have been unable to obtain any experimental evidence for the existence of specific characters in the pathogenicity of strains from erysipelas, nor were we able to distinguish between toxins obtained from erysipelas strains and those from scarlatinal strains.[5]

A Unitarian Interpretation.

I now propose to attempt an interpretation of the clinical and epidemiological features of streptococcal diseases accepting as basis the "unitarian" view of the streptococci. Such a sketch can only be made in outline and tentatively drawn. Modern bacteriological and immunological methods provide powerful weapons of investigation which have as yet been only half-heartedly employed in the clinical and epidemiological fields. A more thorough-going application of these methods would undoubtedly clear up some of the difficulty which at present surrounds the inter-relationships of streptococcal disease.

SCARLET FEVER.

It is not necessary to marshall the evidence in favour of the belief that scarlet fever is entirely an infection with hæmolytic streptococci. This has been done many times during the past few years and it would be difficult to find any serious flaw in the evidence. Uncomplicated scarlet fever may be looked upon in the main as a local infection of the nasopharynx due to hæmolytic streptococci with little if any deep penetration of the micro-organism, but accompanied by a considerable absorption of its erythrogenic toxin. Blake and Trask[6] have actually shown that the toxin may reach a high level in the blood of patients in the early stages of scarlet fever. The systemic effects of the infection rapidly disappear with the development of antitoxin in the blood which takes place after the first few days of the disease. The clinical condition obviously suggests that the streptococcus is in a biological phase during which it readily secretes its toxin, a suggestion supported by the observation that the majority of strains from scarlatinal throats are exceptionally powerful producers of toxin in vitro. Some strains, such as the Dochez and Dick strains, maintain their in vitro toxigenic properties uninfluenced by several years of subculture; other strains I have met with appeared to lose their toxigenic power after a few weeks of subculture.

That certain strains remain more constantly in a toxigenic phase than others may be deduced from the work of Griffith and his co-workers. Griffith's four types may be looked upon as epidemic scarlatinal strains, and between 1926 and 1930 Allison[7] found that types *II.* and *III.* accounted for 42·6 per cent. and all four types together for

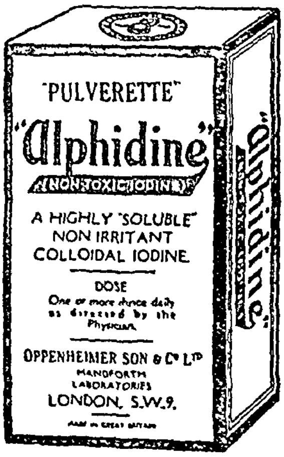
IODINE THERAPY

A NEW OPPENHEIMER PRODUCT

The difficulties and restrictions imposed by the TOXIC and irritant PROPERTIES of Iodine ARE NOW REMOVED by the introduction of



"Alphidine"

(NON-TOXIC IODINE)

(GOVETT PATENT)

"ALPHIDINE" is a NON-TOXIC NON-IRRITANT product of an allotropic colloidal iodine.

Clinical tests in some of the largest London Hospitals establish the non-toxicity and high therapeutic activity of "ALPHIDINE" in Hypothyroidism, Toxæmias, Rheumatic conditions, in fact IN ALL THOSE CASES WHERE IODINE OR THE IODIDES ARE INDICATED.

the Ministry of Health. It is not too much to that our hospital ear and throat departments are nly occupied in dealing with the results of its ages. When we consider that the streptococci nd in this condition have not only obvious pyogenic rer but can also produce the erythrogenic toxin ritro it is very difficult to draw a line between it scarlet fever. Every medical man must have met h epidemics, small or large, in which every feature complication of scarlet fever occurs with the eption of those referable to a high degree of soning with the specific toxin—that is to say the h. Perhaps I may be permitted to quote a small break in my own experience.

child of 8, Dick-positive, contracted an acute septic oat, presumably from her schoolmistress who was ilarly affected. The onset was sudden with high fever, quent pulse, and furred tongue, and the infection spread idly and relatively painlessly to the middle ear on both s. The disease was transmitted in rapid succession wo adults in the same household. In both the latter disease was severe but no complications followed. m the throat of each of the three cases an almost pure ture of hæmolytic streptococci was obtained. These ptococci were found in the laboratory to be moderately d producers of erythrogenic toxin.

f, as we could no doubt have done experimentally, had injected the toxin thus made we would have npleted the picture of scarlet fever. The following tance, also in my own experience, illustrates but a different way the difficulties of drawing a sharp tinction between these throat conditions.

carlet fever had broken out in a school and the school closed. Three children who were not thought to have n in particularly close contact with infection were t home and were isolated very completely from other ldren by an intelligent mother. One child then developed nild pyrexia and septic sore-throat and this was soon owed by the development of a faint patchy rash not all characteristic of scarlet fever. This child was at e isolated from her fellows. A day later another of children developed fever and sore-throat, without a ce of rash. The second victim was promptly isolated h her already affected sister. Both children were k-positive and from the throat of each a profuse growth hæmolytic streptococci was obtained. The streptococci lated were moderately potent producers of erythrogenic in *in vitro*. The rash of the first child did not give ultz-Charlton blanching; it was indeed of a type suitable for the application of the test.

At the end of a week the two affected children had overed from their illness. They were retested by the k test and found still fully positive and the cultures from ir throats showed only a few hæmolytic colonies. On the lications of those observations it was considered that disease was not likely to be scarlet fever and as isolation angements were proving a difficult domestic problem it s decided to release the two elder children from quarantine d allow them to mix with their little sister who was also ck-positive. Two days later this child developed a h fever and sore-throat and in another 24 hours was vered with a typical scarlet rash. From this child also almost pure culture of hæmolytic streptococci was tained, though the throat had been negative at the lier examination. All these children were being carefully lated from other children and there was no known case infection in the immediate neighbourhood.

Such a sequence suggests strongly that the third d typical case had been generated in direct ccession to the other two cases which certainly uld not have been diagnosed as scarlet fever. he process involved seemed closely similar to the altation of virulence obtained in the laboratory animal passage. It is interesting to conjecture hat would have happened if nature's experiment d been allowed to continue without interference d the two recovered, but still Dick-positive elder ildren had been re-exposed to the infection which ey had themselves so obviously propagated. any outbreaks are recorded in which sore-throat ithout rash and typical scarlet fever seem to have been propagated indifferently, including recent instances reported by Stevens and Dochez[16] and by Butler,[17] and Glover and Griffith.[18] In most of these epidemics there has been no record of the Dick reaction of the infected individual, so we cannot easily separate the contribution of parasite and host in producing such variable effects. Since Dick testing has been carried out it has been repeatedly observed that Dick-negative individuals appeared to contract septic throats from scarlatinal patients without showing any sign of rash (Stevens,[19] Nicholls,[20] and others). These various anomalies of streptococcal infection illustrate how impossible it is to give to streptococcal diseases separate clinical names which will imply any specific ætiology.

The Dicks[21] in 1921, in a series of 30 volunteers, produced sore-throat without rash in seven by inoculating their throats with scarlatinal streptococci. Subsequently they found that the same scarlatinal streptococcus could produce typical scarlet fever in some patients and simple sore-throat in others. More recently again they have shown in another human experiment that streptococci from erysipelas inoculated into the throats of five volunteers produced an acute sore-throat in three. Unfortunately the susceptibility of the subjects as judged by the Dick test is not indicated in any of these experiments. We may well ask ourselves what would happen if a streptococcus from a case of erysipelas or suppuration, selected for its high toxigenic power, were inoculated into the throat of a Dick-positive child. The experiment might be crucial for the unitarian view.

It has been, I think, the belief of nearly all experienced observers from the time of Withering to the present day that scarlatinal epidemics may arise by the gradual development of sore-throat cases and eventually die away in atypical cases before the epidemic is finally extinguished. Withering[22] indeed held the view that scarlet fever as he saw it in Birmingham in 1778 and what Fothergill and Huxham described as ulcerated sore-throat are one species of disease, "that they owe their existence to the same specific contagion; that the varieties in their appearance depend upon contingent circumstances, and that the greatest differences are not greater than those of distinct and confluent small-pox." Are we to name these epidemics sore-throat or scarlet fever? Surely it is simpler to suppose that the streptococcus, in the first place non-scarlatinal, has exalted its toxigenicity by passage from individual to individual until it arrives at a phase when it can produce scarlet fever in almost every Dick-positive individual it invades. And if we recognise that so many streptococci from normal persons and those affected with non-scarlatinal diseases have the capacity for producing the erythrogenic toxin, are we not forced to admit the possibility that almost any hæmolytic streptococcus may at times generate scarlet fever?

The view here expressed obtains support from the recent work of Glover and Griffith[18] on school epidemics of naso-pharyngeal disease. The gist of this as it affects the present subject is that these workers have shown that when epidemics of influenza, severe common cold, measles, and tonsillitis occur in schools there appears to be an exaltation of the epidemic activities of hæmolytic streptococci both in the pyogenic and the erythrotoxic direction. Not only do such pyogenic affections as otitis and mastoid disease become common, but cases of scarlet fever may arise apparently de novo. These observations are of great interest, for they afford a handsome confirmation of the *unitarian view*, and one that we had every right to expect ex hypothesi.

The reverse also seems to hold, that because a hæmolytic streptococcus is derived from a case of scarlet fever it is by no means necessarily capable of

63·4 per cent. of 600 cases observed in England. Excepting for their peculiarities in agglutination Griffith's strains *show only quantitative differences from other strains of hæmolytic streptococci, and we are fortunate in obtaining* knowledge of their serological peculiarities.

The streptococci occurring in scarlet fever, at least in the disease as we see it to-day, are much less active in their pyogenic and invasive than in their toxigenic properties, but the pyogenic and invasive properties show themselves in the complications—from local suppurations which are still sufficiently common to septicæmia which is fortunately more rare. I think that there is little doubt from the history of the older and more fatal epidemics of scarlet fever that at one time the pyogenic and invasive factors were very much more important than at present. The great and fatal epidemics of the latter part of the eighteenth and the earlier part of the nineteenth centuries seem to have owed their terrors to the virulence of their pyogenic effects rather than to symptoms ascribable to an exaltation in the power of producing erythrogenic toxin.

SURGICAL SCARLET FEVER.

Few forms of streptococcal disease raise more interesting problems in relationship to the "unitarian" view than the so-called surgical scarlet fever. On the whole it is a subject with a meagre literature; Alice Hamilton [8] in an excellent review estimated that in 1904 there were useful records of less than 200 such cases; but it attracted considerable attention in the 'sixties and 'seventies of last century.

Howse,[9] at that time a surgeon to Guy's Hospital, gives an excellent description of an epidemic occurring in the Astley Cooper ward of that hospital in 1878. He quite clearly recognised that these instances following surgical operations and burns could not be distinguished from ordinary scarlet fever, but he frequently found it difficult *to explain how they arose and he suggests that before the* introduction of Listerian methods such cases frequently merged into septicæmia.

In the same volume of the *Guy's Hospital Reports* [10] there also appears an article which gives a very complete account of cases of surgical scarlet fever occurring at the Evelina Hospital during the 'seventies. The material was provided by W. E. Paley but was worked up with a commentary by James Goodhart. Goodhart came to the conclusion that these were true cases of scarlet fever, and from a study of the grouping of them he considered that the infection passed from patient to patient. He adds that almost all the patients were removed to the fever ward yet there was no instance of them afterwards contracting scarlet fever there.

Sir James Paget [11] in a clinical lecture given at St. Bartholomew's Hospital in 1863 devoted considerable attention to surgical scarlet fever. "By some," he says, "these cases may be supposed to have been only casual coincidences of scarlatina with surgical diseases, but, if this were so, we ought to find a proportionate number of cases among surgical patients not operated upon. But this does not happen."

At the time that these observers wrote the specific propagation of disease was more or less rigidly held and although a typical scarlet fever case could rarely be found to account for the origin of the infection it was believed that it did arise from such a source. A very instructive case was reported in the *British Medical Journal* in 1879 by Ffolliott [12] of Peshawar. A private of the Fusiliers at Ali Musjid, carelessly threw a lighted match on some gun-powder and was severely burnt on the leg, arms, and face. Four days later he developed a typical scarlatinal rash which ran a typical course and was followed by desquamation. Ffolliott, though he admits that scarlet fever was not unknown in India, had never encountered a case in twelve years' service and there was no such disease known in the camp or its surroundings. Joseph Fayrer, whose experience in Indian practice was at that time unrivalled, stated that he had only seen two cases of scarlet fever in India, both in European children and both clearly traceable to a box of infectious clothes sent out in a recently arrived steamer. This seems to be a particularly clear case of surgical scarlet fever arising de novo, but it will be generally admitted that it is usually impossible to trace these cases to a definitely scarlatinal source of infection. A passage from Creighton implying a unitarian opinion is worth quoting as indicating the views of a very acute student of epidemic disease. He states:—

> "It happens from time to time in surgical wards of hospitals for children where many cases of suppurating diseases (especially of the bones or joints) are aggregated and kept together, that groups of the patients acquire a *scarlet rash, or an erysipelas rash, or a hybrid form of* rash—along with the constitutional symptoms of scarlatina," and he adds, "it is not without significance that there may be an element of erysipelas in such cases." [13]

The so-called surgical scarlet fever has not yet been adequately investigated by modern methods. There seems little doubt that on the surface of burns and extensive wounds the conditions for the multiplication and activity of streptococci are closely similar to those obtaining in the throat. Deep invasion from established granulating surfaces does not readily take place, but toxin production and absorption are probably little hampered. Thus, if the streptococcus reaches a sufficiently toxigenic level we can understand that a condition outwardly resembling scarlet fever may take place as a result of surface infection of a wound and it is unnecessary to assume a pre-existing scarlatinal source. Very few direct bacteriological observations have been made on these cases which might permit us to assess the relative parts played by throat infection and wound infection. Toyoda [14] states that the throats of seven cases of surgical scarlet fever were negative for hæmolytic streptococci and in a recent case which has come under my notice of a child suffering from a burn who developed scarlet fever without there being any obvious scarlatinal source of infection, the throat was negative, while the swabs from the surface of the burn grew a copious and almost pure culture of hæmolytic streptococci. It is worthy of note that while ordinary scarlet fever has occasionally been recorded as having been propagated from a surgical case, this is by no means the rule. It would be interesting to know whether surgical scarlet fever tends to occur, as we should expect, in Dick-positive persons, whether the reaction becomes negative at the end of the disease, and whether the early rash in such cases regularly gives a positive Schultz-Charlton reaction as it certainly did in a case recently in University College Hospital.

INFECTIOUS SORE-THROAT.

Under the designation of streptococcal sore-throat we probably have to recognise more than one ætiological entity. There is a common sore-throat, amounting to little more than a dryness of the pharynx, which is often found to be associated with a profuse growth of streptococci of the non-hæmolytic series. There is also the well-recognised "septic" type of infectious sore-throat which is almost invariably associated with the presence of hæmolytic streptococci. That this is a highly infectious condition is generally admitted, but considering the enormous toll of ill-health and permanent disability it exacts from the ordinary population it has been given little enough bacteriological and epidemiological attention, though this omission is now being made good by the work of Glover [15] and his colleagues type of case, which as John Hunter says, "Spreads r a prodigious surface of skin, while it does not ct even the cellular membrane beneath," as due a widespread superficial spread of infection along planes of the skin proper and accompanied by arked local production of the erythrogenic toxin. es streptococcal antitoxin block the advance of fiery erythema of such cases? Are such cases k-positive at onset and does their reaction become ative coincidently with the disappearance of nptoms? These are questions which as yet ve been insufficiently answered, nevertheless their swers might lead to a better understanding of the thogenesis of erysipelas. We must, however, ognise that there is another clinical condition ually classed under the name of erysipelas, the called phlegmonous erysipelas which is a cellu-is of peculiar distribution rather than infection the skin. In many of such cases the bright scarla-iform rash is absent, hence it is not necessary to voke the agency of erythrogenic toxin in explanation. or is it a disease likely to be confined to the ck-positive.

While it has been recognised for several generations at erysipelas is a contagious disease, propagating elf not only as erysipelas but in other septic anifestations, it is very rare indeed to find it opagated with anything like the uniformity of arlet fever. But there is reason to suppose that various occasions in the past erysipelas has tained an epidemic "constitution"—to use the d word—in which it could propagate itself virulently d with great consistency. Brereton,[42] of Dublin, 1826 described an epidemic in which seven cases facial erysipelas (three in contiguous beds) occurred ithin four days in one hospital and many other stances of epidemic spread are referred to in illmann's [43] well-known work on erysipelas published 1880.

PUERPERAL FEVER.

In pre-Listerian days puerperal fever, like erysipelas, as a disease of institutions, and the great majority f epidemics which Hirsch records took place in the ospitals, which were often veritably death-traps o the unfortunate women who entered them. The anitary reform of lying-in hospitals, of which Hirsch imself was so ardent an advocate, appears to have ed to a very different distribution of cases, so that n recent years research has found itself seriously andicapped because the disease is met with so arely in hospitals and the enthusiastic band of workers who have recently in England reopened the ttack against the maternal mortality shown in he Registrar-General's Returns have found it ifficult to find enough collected cases for their nquiries and study.

All modern bacteriological investigation has confirmed the view that serious puerperal infection is nearly always due to the hæmolytic streptococci and the most recent work has been mainly concerned in tracing the paths by which these bacteria reach the patient. Nor has modern work indicated that we can pick and choose between hæmolytic streptococci with regard to their potency in generating puerperal infection. The parturient uterus, as the older observers surmised, shows itself vulnerable to hæmolytic streptococci from the most diverse sources and of the most diverse types as judged by the laboratory tests now in use. Fortunately we can no longer study the terrible outbreaks of concurrent erysipelas and puerperal fever of which we read in medical writings of the early nineteenth century, admirably collected and studied by Hirsch.[44] It should be remembered too, that apart from cases of erysipelas generating puerperal fever there are many instances on record of the reverse process, in which puerperal fever has appeared to generate erysipelas; instance the now happily almost extinct erysipelas neonatorum of which Trousseau [45] has left us such an excellent account. But it is possible to illustrate the common potentialities of the hæmolytic streptococcus by the work that has been done in study of the sporadic and scattered cases of this scourge of maternity, for bacteriology can be brought into play when the problem is too minute for the coarser methods of epidemiological inquiry. Of this recent work the most interesting results seem to me to have been those in which infection has been traced from person to person by bacteriological methods which one might almost compare with the methods used in the detection of crime. In this work of tracing the individual strain streptococcus in its nefarious career, Taylor and Wright [46] have used as their "marks of identification" the cultural and *fermentative peculiarities* of the infecting streptococcus, while J. Smith [47] has employed the more delicate criterion of its antigenic make-up. Taylor and Wright and also Smith recognise that infection with the hæmolytic streptococci which are present in the genital canal in 2 or 3 per cent. of normal labours is a negligible factor in the production of puerperal sepsis compared with that of streptococci which reach the uterus after labour. Thus we have bacteriological confirmation of the older epidemiological views of Charles White, Oliver Wendell Holmes, and Semmelweis which have for long been the basis of obstetric practice in the prevention of puerperal sepsis.

Of 13 cases of puerperal fever due to hæmolytic streptococci studied by Smith, all but one appeared from the evidence of agglutination tests to have been derived from a source of infection outside the patient herself. One case, however, he records in which the source of infection obviously arose from a septic focus on the hand of the patient herself. In one case of septic abortion he found that the streptococcus isolated from the uterus was serologically identical with that isolated from the patient's nose. In two of Taylor and Wright's cases the source of infection appeared to be the patient's own throat, though an extrinsic source for the uterine infection was usually found. It seems then that an infection against which the patient is not prepared carries much more risk than self-infection with the streptococcus already present in the patient and with which she has struck some sort of a stable balance. The observations of these modern workers on the minutiæ of epidemic spread are an encouragement to redoubled aseptic precautions at childbirth, because they emphasise the importance of sources of infection, both within and without the patient, which are so trivial in outward appearance as to escape notice.

The connexion between puerperal fever and scarlet fever is by no means so clear as that between puerperal fever and erysipelas, and in the past many contrary opinions have been expressed upon it. As bearing on the interchangeability of puerperal and scarlatinal infection data derived from pre-Listerian records diverge considerably from those of modern sources. Withering, having heard of three successive deaths following scarlet fever in the puerperium, came to the conclusion that "it was particularly fatal to lying-in women," a view later held by Trousseau and more producing scarlet fever in other persons. It is generally recognised that anything up to 50 per cent. of scarlet fever patients kept for a reasonable period in an isolation hospital have in their throats hæmolytic streptococci which are in many instances serologically of the same type as the original infecting micro-organisms.[23] Such patients when they are discharged to their homes only generate a very small proportion of "return cases," rarely more than 2 or 3 per cent. This gives ground for the presumption that during sojourn in the throats of convalescents the streptococcus passes out of the epidemic scarlatinal phase.

Creighton's remark may here be quoted that "Every medical practitioner knows, if some laymen and legislators do not, that scarlatina is sometimes highly contagious, and sometimes hardly contagious at all," much the same view as that held by that fine observer Robert Willan over fifty years before.

The care which is taken in modern hospitals to avoid the aggregation of septic streptococcal cases prevents us from seeing nowadays the natural propagation and exaltation of streptococcal epidemics lamentably common in such institutions during the earlier part of the last century. But in one department at least of hospital practice from causes which are not at all easily controlled, something of the old epidemiological *mis-en-scène* is maintained. I refer to the throat and ear departments of hospitals. Here from the nature of the work, it is difficult to prevent the aggregation of septic cases and quasi-septic cases (under which heading we must, I think, include the majority of tonsillectomy cases). In many such departments scarlet fever is a recurring trouble though every care is taken to prevent the entrance of frankly scarlatinal infection. Anna Williams [24] has found that from 25 cases of excised tonsils with no history of recent exposure to scarlet fever, 14 strains of hæmolytic streptococci were isolated and of these, six produced toxic filtrates neutralised by convalescent scarlet fever serum. It does not then seem necessary to regard scarlatinal cases occurring under these conditions as due to the introduction of scarlet fever, as such, into the hospital. If there is anything in the conception of exaltation of virulence or toxigenicity by human passage we have here ideal conditions for both dissemination and exaltation. Even if we exclude the special problem of scarlet fever from consideration, the epidemiological conditions met with in throat wards of hospitals are worthy of more study than seems to have been given to them. Is it not to beg the question to accept that the cases of otitis and mastoid disease which sufficiently frequently complicate tonsillectomy are due merely to the "stirring up" of intrinsic infection? That latent infection can readily be stirred up by operative injury no one would deny, but in "stirring up" a latent infection in the individual due to such a versatile, dangerous, and readily disseminable bacterium as the hæmolytic streptococcus may not we also, by passing a strain from one who is tolerant to it to one who is not, be "stirring up" an epidemic? I have been able to find no statistics bearing on the relative frequency of complications after tonsillectomy in patients operated upon in hospitals and in private practice, but if they were available they might be interesting. Joe [25] quotes the saying of an ear and throat surgeon who said "that sometimes while the patients on whom he had performed tonsillectomy were contracting scarlet fever, the patients on whom he had performed mastoid operations were beginning to suffer from erysipelas." This is a modern saying, but it will have a familiar ring to anyone who has looked into the history of septic infections in pre-Listerian times.†

Rheumatic Fever.—I do not propose to consider the possible rôle of the hæmolytic streptococci in the causation of rheumatic fever though this has been the subject of much interesting work by Schlesinger,[26] Coburn,[27] Sheldon, Collis,[29] and Glover and Griffith [30] during the last two or three years. The admirable epidemiological inquiries of Glover and Griffith give much weight to the views originally put forward by Mantle,[31] of Durham, in 1885, as to the close connexion between tonsillitis and rheumatic disease, but the majority of those who are most conversant with the clinical and pathological features of rheumatic disease seem to find it difficult to link them with the known pathological features of infection with the hæmolytic streptococci. On the principle laid down by Hume in his "Essay on Miracles," that the greater the improbability the more rigid should be the proof, we can only await with caution further developments along this line of work.

ERYSIPELAS.

Fehleisen [32] in his classical paper written in 1882 records having produced typical erysipelas in six out of seven human beings by scratching into their skins a pure culture of a streptococcus from erysipelas. Fehleisen held that his coccus was not identical with the streptococcus which Ogston had previously isolated from pus. The specificity of the erysipelas organism was however, soon challenged on morphological, cultural, and experimental grounds by Widal,[33] E. Fränkel,[34] Petruschky,[35] Marmorek,[36] W. Bulloch,[37] and others. Not only did Petruschky show that human erysipelas could be produced by inoculating pure cultures from an abscess, but he and others found that an essentially similar disease could be produced by inoculating staphylococci and *Bact. coli* into the skin. Panton and Adams [38] record an instance of an experiment, accidentally performed, in which the same streptococcus introduced into two separate lesions gave rise to local suppuration in one place and typical erysipelas in the other, and Tillmanns [39] refers to an experiment in which deep suppuration was produced in man by the inoculation of a pure culture of erysipelas streptococcus. Even more severe results followed the inoculation of Fehleisen's streptococcus as in the fatal case recorded by Janicke and A. Neisser [40] as well as two fatal cases mentioned by Coley,[41] and there may well have been other such cases which for obvious reasons were not published.

John Hunter once expressed the view that erysipelas was "the result of a peculiar constitution in the patient without which the same irritation would have resulted in common inflammation." We now tend to translate what Hunter called "peculiar constitution" into immunological terms and immunological research might do much to clear up the mystery of the peculiar features of erysipelas. The tendency of erysipelas simplex to clear up within a few days is so closely analogous to the cure of scarlet fever that it may well be associated with the development of immunity to the erythrogenic toxin of the streptococci. Some observers have stated that they have been able to blanch the advancing margin of the erysipelas rash with streptococcal antitoxin, others however have failed. Confusion may have arisen in the choice of clinical material for these experiments. The bright red erysipelas simplex—the St. Anthony's fire of the countryside—would most suggest the effect of the erythrogenic toxin. We could interpret ppears worth while to administer the erythrogenic itoxin to such patients.

---

† cf. with a remark of Solly's quoted by Braxton Hicks, (Brit. Med. Jour., 1878, ii., 796). "Whenever a case of surgery in private takes on a highly phlegmonous appearance, I am always sure to find break out in the inmates either erysipelas or scarlatina."

Inadequacy of Theory of Specificity.

The haphazard sequences and relationships which iave selected from an almost unlimited series, old d new, seem to constitute a *reductio ad absurdum* any specificity view of the hæmolytic strepto- cci and the common human diseases with which ey are related. It is as impossible to separate e several clinical and epidemiological forms of eptococcal disease as it is to distinguish specifically e streptococci found in connexion with them. ie attitude of the physician when faced with the tual practical clinical and epidemiological problems these diseases must largely depend upon the view takes on this matter, and one or other view he ust take as a working hypothesis and as a scheme r holding together the large number of facts which e available on the subject of the hæmolytic strepto- occi and the diseases associated with them. The nitarian view is consonant with the admitted ilure of the bacteriologist to subclassify the group. is in consonance with the curious sequences of ropagation which may be observed in streptococcal isease. It does something to explain the mysterious irth of streptococcal epidemics and the failure f hospital and other forms of isolation to control he incidence of scarlet fever.[54] It permits a escription of the hæmolytic streptococci daily met ith in disease under one name, and it calls a truce o what Topley and Wilson call the "riot of hristening" which has brought so much confusion nto the study of this group. In designating a ommon toxin throughout the group and defining he clinical effects of that toxin it indicates both he value and the limitations of antitoxin treatment nd finally it discourages the use of sera the only pecific thing about which is their label.

Decline of Streptococcal Infection.

Anyone who has traced the history of the streptococcal diseases from the first adequate records of the eighteenth century to the present day must needs be struck by the gradual decline in severity of epidemics which seems to have begun in the days of Lister and the pioneers of bacteriology and still goes on. In the war of attrition between streptococci and the human race civilised man seems to be gradually emerging as the victor. This is not, I think, because the human race has become less susceptible, nor because any dramatic methods of dealing specifically with streptococcal disease have been forthcoming, but rather because the small obstacles set in the way of epidemic spread have slowly but surely had the hoped-for effect, possibly by placing some control on the passage and exaltation of the infecting agent. The individual source of infection in streptococcal disease only too often eludes us and is likely to continue to do so, but we no longer expect to see the terrifying fatality of puerperal fever, wound infection, erysipelas, and malignant scarlet fever which was familiar in by-gone days. Some "accessible link"—to use Topley's expression—in the propagation of streptococcal disease seems to have been reached if only by our ill-guided gropings. For fifty years this country has been nearly free from the dreaded scarlet fever which a century ago decimated townships and exterminated families.[55] Fifty years is a long interval in an epidemic periodicity and we may reasonably hope that the old type of epidemic has disappeared never to return, a consummation perhaps of all the hygienic measures, separately inconsiderable, that have gone to make up modern preventive medicine.

NORTH MIDDLESEX COUNTY HOSPITAL.—In his report of the work of this hospital for the nine months ended Dec. 31st, 1930, Lieut.-Colonel Spencer Mort, the medical superintendent, states that the total admissions, including 862 births, were 8216. There were 22,650 out-patients not including pensioners. The number of deaths was 1077, but more than 10 per cent. of these patients died within 48 hours of admission and 53 per cent. were over 60 years of age. "The death-rate, therefore, conveys no exact expression of the utility of the hospital *as a whole*," *Colonel Mort* says, "but presents partly the conclusion of cases from other hospitals, whose statistics benefit at our expense." The mental wards are condemned as unsuitable.

recently by Caiger,[48] who stated that in his own experience of cases in which the rash appeared within four days of parturition the mortality was over 70 per cent., puerperal septicæmia usually supervening. Braxton Hicks in 1868 stated that in his own practice "about three-fourths of the puerperal fever he saw was somehow mixed up *with scarlet fever*," and in the Transactions of the Obstetrical Society of 1871[49] he gives an excellent account of his views as to the relationship between the puerperal fevers, recording many cases illustrating my present theme. Andrewes and Gordon[50] in their paper report what they describe as a puzzling series of cases in which a scarlet fever case appeared to generate not only other cases of scarlet fever but also a fatal case of puerperal fever which in turn generated scarlet fever in the nurse who was attending her. On the other hand two such well-known authorities as Goodall[51] and Ker[52] express the opinion that scarlet fever usually runs a mild and typical course in puerperal women. Goodall, however, admits that in many instances of puerperal septicæmia the only traceable source of infection has been cases of scarlet fever, and Ker records one case of a woman dying as the result of both puerperal infection and scarlatina anginosa. It appears then that, although the present mild variety of scarlet fever is not necessarily dangerous to the parturient woman, streptococci derived from scarlet fever may at times produce the severest puerperal fever and that this risk was greater in those days when scarlet fever epidemics were more definitely pyogenic in character.

There seems little doubt that there are two conditions occurring in the puerperium which may be diagnosed as scarlet fever, the one an ordinary scarlet fever due to primary faucial infection, and the other due to primary infection of the uterus itself with a streptococcus of high toxigenic power. The latter merges into other forms of puerperal fever from which it can only be separated by its severity.

Hypothetical Scheme for Streptococcal Diseases.

—	Toxigenicity of strepto-cocci in vivo.	Susceptibility of patient judged by Dick test.	Primary site of infection.
Scarlet fever ..	+ +	+	Throat.
Acute pharyngitis = S.F. sine eruptione	+ +	–	,,

Cellulitis and pink lymphatics ..	+	+	Cellular tissue.
Cellulitis; no pink lymphatics ..	{ + ±	– + or –	,,
Surgical scarlet fever	+ +	+	Large surfaces; (little invasion, profuse growth).

I have put out in a rough scheme (see Table) what I conceive to be the various clinical, pathological, and immunological entities of streptococcal origin which are met with during the puerperium and I have extended the scheme to cover other streptococcal entities. The first column indicates the presence of erythrogenic toxæmia in the clinical aspect of the disease. The sign ± in this column merely expresses that while there may be some clinical signs suggesting specific toxæmia, this is not *in most cases of the disease in question* a prominent feature, not enough at any rate to give rise to a definite rash. It will be seen that three immunologically separate conditions are to be considered under the name of puerperal fever quite apart from simple scarlet fever (1) a condition in Dick-positive women in which generalised rash is present and which may be considered as scarlet fever due to infection of the uterus with a highly toxigenic strain; and conditions without rash (2) those in either Dick-negative or positive women where the streptococcus in the uterus is not sufficiently toxigenic to produce rash; and (3) those in Dick-negative women in which, though the toxigenicity of the streptococcus in the uterus is marked, there is sufficient circulatory antitoxin present to prevent the rash and other manifestations of the erythrogenic toxin. In any or all of these conditions septicæmia may occur and dominate the clinical picture.

STREPTOCOCCAL WOUNDS.

It would not be in my province or competence to attempt to describe the protean surgical diseases due to the infection of wounds with hæmolytic streptococci. I have already discussed two special manifestations of wound infection, surgical scarlet fever and erysipelas, but apart from these much material could be quoted in support of a unitarian hypothesis of the causation of streptococcal disease. It was long ago noted by surgeons that a gentle pressure on the course of one of the pink lymphatics which are seen in cases of streptococcal wounds would prevent the proximal spread of the redness and it was recognised that this could not be due to blocking the advance of living bacteria. Some years ago[53] I pointed out that a similar radiation of pink lymphatic vessels spread from the site of an intradermic injection of a sufficient dose of the erythrogenic toxin of a scarlatinal strain and the observation has since been frequently confirmed. It would seem then that the reddening of the lymphatics so characteristic of streptococcal wound infection is produced by the same toxin as produces the rash of scarlet fever. Streptococcal lymphangitis can thus be looked upon as a kind of "miniature" surgical scarlet fever. The toxin removed by the lymphatics presumably reaches the general circulation and probably adds its quantum to the misfortunes of the patient. Not uncommonly a more or less generalised scarlatiniform rash occurs in such cases. Erysipelas may develop at the edges of the wound and septicæmia may follow the inward spread of the infection. Thus even such a *simple* form of streptococcal disease as an infected wound illustrates streptococcal potentialities that can only be simply explained by the unitarian hypothesis. We lack the immunological data which might help to widen our knowledge of wound infection. I know of no observations correlating the Dick test with the occurrence of "lymphangitis" of the peculiar streptococcal type. John Hunter thought that the condition depended upon the "constitution" of the patient and it may well be that only those develop "pink lymphatics" who are positive to the Dick test. At least in the absence of more precise knowledge mation of differences in clinical results with long short times of exposure? I think it must be tted that while it is quite possible to invoke aspect of cell activity as a rational explanation hat is happening, there are other important bilities. For this reason it may be well if we nise that while these studies on the particular es of activity in the cell are fundamental in acter, they are not necessarily, though they may he key to the position as regards cell reactions adiation.

few words may be said about other ways in h these clinical differences can be visualised. ving cell represents a vast complex which is ehow in equilibrium, and the various equilibria maintained in spite of an extraordinary number actors which are always tending to upset them ne way or another. These equilibria differ from equilibria considered in physics, because they are ble of adjustment over such a very wide range ction. The whole organisation of the cell, being nally adapted to the processes of repair, growth, tiplication, and so on, can cope with forces whose ons on many inert media quickly upset the nal conditions of equilibrium, but in the case of cell they do not do so unless certain limits are hed. For instance, practically any normal organ he body can stand some dose of X rays without ng any recognisable reaction, no skin reaction, epilation, no blistering, no sterilisation, &c., and in itself argues that the processes set up in the by radiation can be supported within certain ts. Now without doubt, when X rays and gamma s are absorbed by the tissues, the initial process is liberation of electrons in situ and the main effect duced by these electrons, when they in turn are orbed by the immediate tissues, is to produce condition known as ionisation; but it should recognised that this ionisation is only likely to important when it happens to certain classes of mical bodies. The ordinary electrolytes of the ly will not be affected; colloids, yes, if posi- ely charged, not if negatively charged, and hough some processes of oxidation may be iated, those of reduction appear to be almost likely, according to recent work by Colwell.[*]

There is, however, one class of bodies playing an portant part in cell processes—namely, intracellular ymes—which appear to be influenced by radiation an extent which must be taken into account here. may prove to be a significant fact that the curves strating the rate of destruction by radiation of tain simple forms of vegetable and animal cells, d of enzymes, are so similar in their general aracteristics. It may, of course, be found that this only a similarity with no causative link between em. Enzymes play an important rôle in cell life. d one aspect of their activity is shown in recent rk by Chambers and Scott. If, for instance, an planted tumour of J.R.S. be removed from a rat, inced up and incubated with saline for various riods of time, a cellular extract from it seems dowed with two properties when used. If the riod of incubation is long, and this extract is injected to rats, the animals are made more sensitive to oculations of tumour cells; if the period of incuba- on is short, say less than two hours, the extract s the property of making rats immune to a certain tent.

The bearing of such observations on the subject this paper may now be discussed. The whole question of immunity towards implantations of cancer in animals is a very big one and a very much disputed one, yet there are many who will agree that if you can protect an animal against an inoculation of cancer cells towards which it is normally susceptible, you have gone some way in a therapeutic problem. Now if irradiation of a tumour is followed by its disappearance, and if in the act of disappearance (autolysis or disintegration) substances may be formed which have the potentiality of either making the organism more susceptible or, on the other hand, making it immune to tumour growth, then it might be inferred that the disappearance of tumours in the body may either be followed by conditions of increased susceptibility or immunity in the body of the host. Experimentally the condition of necrosis is one in which cellular extracts can be obtained which produce conditions of increased susceptibility to tumour growth; and necrosis of the tissues is one of the danger signals in radiotherapy. It may be too early to apply this principle in therapeutics, but it may well be that some of these obscure kinds of reaction *going on in the body have more to do with the essential* actions of radiation than can yet positively be claimed for them.

Theories of Indirect Action.

Any effects of radiation upon the body other than the direct effect on the malignant cells are included in the term indirect action. It may be useful to divide the subject into three sections: (1) normal structures, contiguous to the malignant growth; (2) the circulatory system; and (3) the portions of the body remote from the growth. Dominici was perhaps the first to point out the importance of the part played by the normal cells in the vicinity of a malignant growth after gamma irradiation. He was able to show that in the course of several days after a dose of radiation there was an accumulation of plasma cells and lymphocytes in the stroma, and that these invading cells had a great deal to do with the subsequent disappearance of the growth. Experimental studies in immune and irradiated rats support the view that local cellular processes play a sane part in deciding the trend of events, though the immune condition is general.

With regard to the circulatory system, an enormous amount of work has been done showing the effects of X and gamma rays upon the blood stream in man and in a large variety of animals. This action has been shown to be largely a destructive one, although not entirely so. Large doses to the body cause a diminution in most of the cells, especially the lymphocytes, extending indeed to a destructive action upon the marrow which, if great enough, leads to death. This so-called destructive action of the radiation upon the blood does not necessarily mean that when cells are withdrawn from the circulation they are destroyed; in some cases no doubt they are, but it is an experimental fact that when the lymphocytes are withdrawn from the circulation of a rat by exposure to a small dose of X rays they return to their original numbers in a very short time. As this process can quickly be repeated, it is perhaps more rational to conclude that it is not a case of destruction but of temporary withdrawal from the circulation. The effect of repeated small doses of radiation upon the body has not been systematically carried out in man, and only to a limited extent in animals; but as far as the experiments go they show that the number of white cells in the circulation can be substantially increased. The effect of X rays and gamma rays on the capillaries should be

NATURE OF THE ACTION OF RADIUM AND X RAYS UPON MALIGNANT GROWTHS.

BY SIDNEY RUSS, C.B.E., D.SC. LOND.,
PROFESSOR OF PHYSICS IN THE UNIVERSITY OF LONDON.
(*From the Barnato-Joel Laboratories, Middlesex Hospital.*)

IN the course of the development of radiotherapy (radium and X rays) opinions have from time to time been advanced as to the nature of the *action* which the rays have upon malignant growths. Suppose, for the purpose of the argument, that the *effect* is the disappearance of these growths, then the question is, what action or series of actions is set up by the radiation which leads to this?

In the first instance opinion naturally inclined to the view that the rays had a direct effect upon the malignant cells, and that this action was in itself quite enough to account for their disappearance. Experimentally it is not a difficult matter to show that X rays or gamma rays in doses such as are commonly used clinically have a direct action upon malignant cells; this is most easily shown by excising animal tumours, exposing the tissue to measured doses of the rays, and then implanting small pieces of it into susceptible animals. The effect of big doses is to prevent the growth of the implantations, and doses smaller than this give rise to a delayed onset or diminished rate of growth, so that a whole range of direct effects is apparent by merely varying the dose of radiation. For a long time, therefore, attention was focused upon what kind of direct action would most probably be induced by the rays, and in consequence a number of suggestions arose about what parts of the cell were most sensitive to radiation. First one chemical component of the cell was suggested, then another, but it cannot be said that the attempt to attribute the change to any particular chemical substance has met with any success or had any constructive value in helping us to visualise the essentials of the processes initiated by radiation.

While these ideas were being developed it was suggested that perhaps after all the action of radiation upon malignant growths might be an indirect one, and that it was not so much what the rays did to the malignant cells as what they did to the normal contiguous structures and to the organism as a whole that brought about the end-result. There was a certain amount of clinical and experimental support for these views, for patients had been given moderate, in fact quite small doses of X rays, certainly not lethal ones, over prolonged periods and had gained benefit from them. There were few records of what might be called disastrous results with this form of treatment. Soon after the adoption of the Erlangen method of giving large doses at a single sitting to patients suffering from malignant disease, there was evidence that these doses could not be given with impunity, and in many cases caused fatal results. From the experimental side there is abundant evidence that heavy doses of X rays or gamma rays are very damaging to the normal tissues and cells of the animal body, but an extraordinary range of vulnerability exists among the tissues, some being very sensitive, others very resistant. On the other hand, experimental evidence has been brought forward to show that small doses of X rays judiciously given appear to help the organism to combat the growth of cancer. For instance, if a small region of the rat's body be X rayed, and the animal is afterwards inoculated with sarcoma cells, these cells proliferate more freely in the non-rayed than in the X rayed tissues; again if the whole rat be given repeated small doses of X rays and sarcoma cells are then implanted they do not grow as rapidly as in the normal untreated animals.

Altogether the evidence seems to show that the action of these rays is partly a direct one and partly an indirect one, and it remains to discuss the nature of these two actions.

Theories of Direct Action.

One of the most significant clinical facts in connexion with radiotherapy is that the effect of a given dose of radiation upon a malignant growth depends upon the time interval over which the dose is spread. This is perhaps shown most strikingly in radium therapy in the treatment of primary growths of the tongue. When these localised growths were treated years ago by the insertion of a few radium tubes of a high intensity for a relatively short time the results were bad. Now, by the use of a larger number of low intensity needles, and prolonging the exposures for seven to ten days, the results are good—so good in fact that, at many clinics, experienced radium therapists will express little doubt about being able to treat a primary lesion in the tongue successfully. It should be borne in mind here that some of the improvement in the results is due to a more even distribution of the radiation. Again, an example may be quoted in the case of X rays. It is probably true to say that the method of Coutard, at the Radium Institute in Paris, of treating malignant glands in the neck by means of repeated small doses of X rays prolonged over a period of several weeks, is better, judging from the results, than the method of administering large doses to such regions in a comparatively short time.

It would be quite unwarranted, from two such groups of cases, to jump to the conclusion that the whole of the *practice of radiotherapy* has to be recast on the lines of small intensities and long times of exposure, for some of the work at the Memorial Hospital, New York, shows the possibilities of treatment with high concentrations of radium for relatively very short times. But the two cases which have been cited do lead us to look afresh at the position and to inquire what particular actions set up by the radiation are responsible for the wide clinical differences noted.

If time makes all this difference, it is possible tha the life-cycle of the cell is operating in some wa to account for these differences. Quite early i experimental studies it was found that some type of cells were more sensitive to radiation in the dividin stage than in the growth stage. Studies of this kin have been continued intermittently and develope notably by Spear and Love at the Strangeway Laboratories. This later work has shown that no only are there stages in cell life which do diffe enormously in their sensitiveness towards a dos of radiation, but that the premitotic stage is particularly sensitive phase in its life, and th inhibitory action of radiation upon growth ca perhaps to a large extent be interpreted as bein due to the prevention of the cell entering the mitoti phase.

Given these facts in a general way, are we entitle to go further and say that they provide a rationa tes this by saying, 'Us used to walk in our sleep, the nurse said, but us didn't know about it'), d she thought the nurses and people were talking ainst her and that she had seen strange faces in ward." It was in consequence of this that she s readmitted to the Devon Mental Hospital on pt. 9th, 1931.

Since her readmission she has been well-behaved d, under careful supervision, has made herself eful in the ward. The "choreiform twitching ovements" are no longer observable, but she has ffered from occasional epileptiform fits in which e bites her lips but not her tongue. She has no aura," nor has she any recollection of her fits, as e is confused for some time afterwards. She does t injure herself in falling, nor does she lose control her sphincters. The sister of the ward reports at the fits are very violent. A bromide mixture as prescribed, and she has had no fits since ct. 30th.

She is periodically depressed, easily upset, and uickly "pulls a long face"; indeed, the rapidity f her *emotional changes remind one of the* disseminated sclerotic or of the encephalitic; but etween-times she takes an interest in things generally nd is cheerful enough when talking to the doctors nd nurses. Though her speech has a tendency to luggishness, and she refers to herself as "us" an expression common to the Devon dialect), here is now no evidence of any speech difficulty, and she answers questions quite readily and ationally.

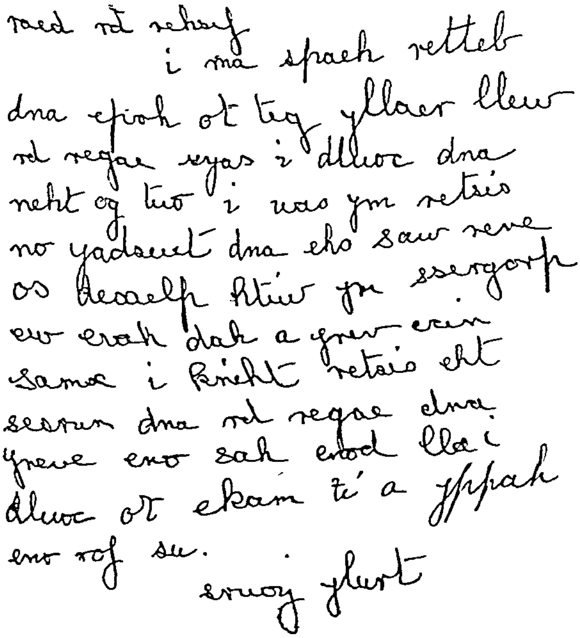
The measurement of any adult's intelligence bristles with difficulties. Nevertheless, we thought hat by putting to her a modified series of Binet-Simon tests (adapted for children up to 16 years), a rough estimate of her intelligence might be formed. She came through the final 16-year examination with flying colours, except for the arithmetical reasoning tests (which are in the 14-year examination); these were very poorly performed. Memory and comprehension tests were very good. Information gained from these intelligence tests, in conjunction with observations on more general lines, indicate that she has an intelligence quotient between 70 and 80 or possibly even between 80 and 90. Classified thus, she would be regarded as a dull or "backward" case. Her backwardness is doubtless chiefly due to her lack of maternal care and poor educational facilities. She "prefers girls' school stories" to the newspapers, which she does not read.

Physical examination revealed no definite abnormality. Her general health is satisfactory, save that she was pale and obviously anæmic on admission; she bas since gained 10 lb. in weight. Her pupils are large, and react well to light and *on* accommodation. She has always worn glasses, and Dr. G. P. Hawker, the consulting ophthalmic surgeon to the Devon Mental Hospital, who saw her before her discharge in 1924, prescribed lenses to correct a −3·5 astigmatism. He has again examined her since her re-admission, and confirms that these are still what she needs. Her deep reflexes are brisk; her knee-jerk gives a sustained reaction of the choreic type. Tests for asynergia reveal a marked incoördination *with the finger-nose test*, particularly when she performed it with the right hand. When, however, she opened her eyes she was able to perform the test without error. She complains of "an irritating tickling" in the ears, giddiness in which the world starts swimming round so that she has to sit down, and of headaches, "right on top of the head, first stabbing, then dull."

READING, WRITING, AND DRAWING.

The real interest of this case revolves round her unusual manner of reading, writing, and drawing. She writes each word backwards, starting on the customary side of the paper—i.e., to the left—and using her right hand (Fig. 1). Each letter symbol, however, is correctly orientated. With her left hand she writes in exactly the same manner, though with less facility, thus:—

FIG. 1.



raed rd rehsif
i ma spaeh retteb

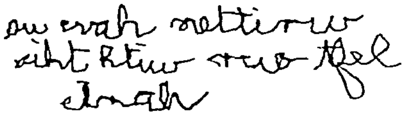
sruoy ylurt

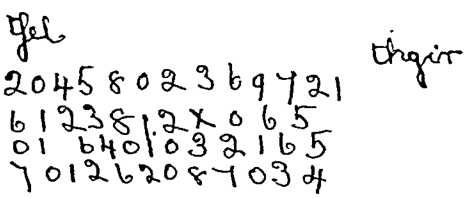


su evah nettirw
siht htiw ruo tfel
dnah

She informs us that she has never been left-handed. Her sister writes normally. The presence or absence of the patient's spectacles does not affect the issue. Her figures are correctly orientated, but, when she is asked to copy a row of numbers she will write them backwards, starting, as for the writing of words, on the correct side of the paper. When asked to copy the following figures,

```
        Left                  Right
  1 2 7 9 6 3 2 0 8 5 4 0 2
      5 6 0 X 2 1 8 3 2 1 6
  5 6 1 2 3 0 1 0 4 6 1 0
  4 3 0 7 8 0 2 6 2 1 0 7
```

this is what she produced:—



tfel thgir
2 0 4 5 8 0 2 3 6 9 7 2 1
6 1 2 3 8 1 2 X 0 6 5
0 1 6 4 0 1 0 3 2 1 6 5
7 0 1 2 6 2 0 8 7 0 3 4

She adds and multiplies in an extraordinary manner (Fig. 2). Thus when requested to add together $\frac{253}{179}$ she turned the paper round and wrote

Ɩㄥ6
Ɛϛᄅ
32121.

Apart from the reversal, this method of addition bears a resemblance to the practice of the aphasic. After adding together two figures which amount mentioned—the treatment of capillary nævi proceeds on the lines of repeated small doses, the ultimate effect being the obliteration of the capillaries.

For our purpose here we may, in the circulatory system, include the function of the blood stream in dealing with bacterial infections. It is the usual practice in the radiological treatment of infected growths to attempt to clear up the infection as far as possible before any irradiation is carried out, otherwise there may be a flare up and rapid death from sepsis. Experimentally it has been shown that heavy doses of X rays to an animal can markedly lower its resistance to bacteria. If, for instance, the abdomen of a cat be given a heavy dose of X rays, all the rest of the animal being protected from the rays, death may ensue in a week with an acute infection of the lungs. It is unthinkable that the function of the blood stream is not of prime importance in the reaction of many malignant growths towards big doses of X rays or gamma rays.

Finally, the indirect action of radiation upon malignant growths must include the action the rays have upon the general physiological functions of the body. Here is a field practically unworked over by physiologists. We are, without doubt, more ignorant of the general physiological effects of X rays and gamma rays than we are of their immediate effects upon cell life, whether malignant or otherwise. It is an encouraging sign that physiologists are now including radiation as an instrument for their use, which may prove not only of direct benefit in purely physiological studies, but which will in turn yield results having an important bearing on radiotherapy.

Conclusion.

The foregoing remarks inevitably bring with them the question as to whether there is any method by which we can indicate which of the many actions produced by the rays are really the most significant. While all these actions are extremely interesting subjects of study, it is a vital matter to know which of them are of primary and which of secondary importance.

One method of approach to the question is to try to correlate the various effects with the doses of radiation which produce them. How wide a range of dose-effect exists, even among the few examples mentioned, may be seen as follows: If we call L the lethal dose—i.e., the dose of X rays or gamma rays which if given to a layer of tumour cells just prevents their growth—then one-tenth of this dose causes an easily recognised reduction in the number of cells in mitosis. Now turn to the action of X rays on colloids; Crowther has shown that the positive colloids may be precipitated by X rays, but the doses required to do this are relatively enormous, about 20 L. Another contrast could be provided by the following: A dose of X rays equal to L/10 would be quite enough if given to a rat to rid the blood stream of more than 90 per cent. of its lymphocytes, yet 20 times this dose could be given without being able to convert 1 per cent. of sugar into dextrin.

If we attempt to evaluate the various actions of these radiations, bearing in mind their order of appearance in the scale of quantity—how some of the vital functions of living tissues are put out of action by a quantity of radiation which has but a trifling action upon their other processes—perhaps the most important classes of action are:—

(1) Those which interfere with or disorganise the delicate processes involved in the division and maturing of cells.

(2) Those which determine the release into the tissues and into the circulation of the products of cells, normal as well as malignant, whose destruction is caused by the rays.

(3) Those which produce changes not only in the content and production of the blood, but also in its power of dealing with infection.

A CASE OF PSEUDO-MIRROR-WRITING

AND SOME OBSERVATIONS.

By Richard Eager, O.B.E., M.D. Aberd.,
MEDICAL SUPERINTENDENT OF THE DEVON MENTAL HOSPITAL;

AND

John W. Fisher, M.R.C.S. Eng., D.P.H., D.P.M.
TEMPORARY ASSISTANT MEDICAL OFFICER AT THE HOSPITAL.

THE exceptional interest of this case, and the fact that we can find no recorded parallel, has encouraged us to give a detailed account of our investigations. That the understanding of abnormalities of writing and drawing has progressed so slowly may perhaps be ascribed to the fact that similar cases have, in the past, been inadequately recorded.

The patient was a domestic servant, 28 years old. She had been admitted at the age of four to the children's home of a workhouse. There she had remained until 14 years of age, when she left to live with a relative. Soon after this (about 1918) she entered the Royal Devon and Exeter Hospital for the treatment of chorea. On July 12th, 1923, she was admitted to the Devon Mental Hospital suffering from "choreiform twitching movements," and was classified as a congenital mental defective. There were no fits, nor did she then show any peculiarity of writing. She was discharged on Sept. 2nd, 1924, and went into service. After a while, however, she had to leave the situation because "shakiness of her hands" caused her to drop trays, teacups, &c.

About four weeks after her discharge, while staying with a friend, she was "taken ill" and she remembered nothing more until she woke up next morning to find herself in bed in her friend's house. This illness seems to have been in the nature of a "fit." She was admitted on Feb. 26th, 1926, to a local infirmary in such condition that—to quote her own words—"she couldn't think, speak, or write, but she could hear what people said to her." Her memory was also defective. She "tried hard to speak, but couldn't get any words out"; a little later, she wrote her wants on a slate, but at first the nurses failed to understand her writing. This seems to be the time when the pseudo-mirror-writing took its origin. It was not long, however, before the nurses tumbled to the meaning. During her stay here, her speech would return at intervals, but never for more than a few days or so at a time. Four months before she left she had a "shock," which brought her speech back and, in her own words, "it never left her again."

In May, 1930, the guardians sent her to an epileptic colony, from whence she went back to an infirmary. Whilst there it is reported that "she attempted to throw herself out of the window and to strangle herself; she wandered about at night (she substanrmed the corresponding letters in their correct rientation : A, B, C, D . . . &c.

MIRROR-WRITING AND SIMILAR ABNORMALITIES.

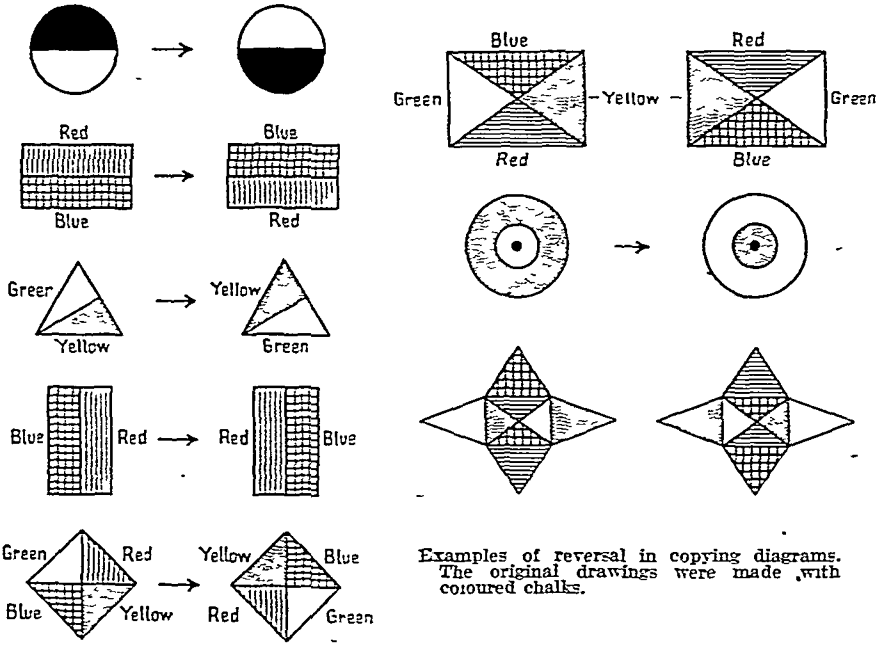
Three salient points emerge: Firstly, that the writing is not true mirror-writing; it is backward writing, with the letters correctly orientated, and written with the right hand in dextrad fashion, from left to right of the paper. This pseudo-mirror-writing, as we have christened it, is unintelligible when reflected in a mirror, save for an isolated word here and there. Secondly, it is associated with upside-down reading and drawing and backward spelling. Thirdly, the pseudo-mirror-writing —and doubtless the associated phenomena—began after the "illness" recorded in the case-history, and that, also about that time, the "choreiform twitching movements" departed and were replaced by frank "fits."

We make no apology for the term pseudo-mirror-writing, although it is in the strict sense an inexactitude, because at first sight the script does indeed suggest mirror-writing, and because the affinity of title does bring out, upon examination, certain common relationships between two distinct phenomena. For the benefit of those who have not made a special study of mirror-writing ("Spiegelschrift"), it would be well to explain that the designation is generally applied to that form of writing which is executed from right to left, with the letters reversed and so arranged that when reflected in a mirror they look like ordinary writing. It is worthy of note that a large number of observers have associated mirror-writing with left-handedness and "eyedness" (Brennan).

Most commonly true mirror-writing is executed with the left hand, either because there is a natural left-handedness (Blom believes that mirror-writing is as normal for left-handed people as conventional writing is for the right-handed) or because some disability of the right hand tends to it. The majority of cases of mirror-writing so far recorded have been observed to follow right-sided hemiplegia. In such cases we can most happily apply the motor hypothesis of Erlenmeyer or other hypotheses based primarily upon bilateral representation in the cerebral cortices. Whilst most common in cases of hemiplegia, true mirror-writing has been observed in a variety of nervous disorders ranging from locomotor ataxia to hysteria. It has occurred under hypnosis and in cases of automatism. Sundry instances of idiots and imbeciles so affected have been recorded. Women are more subject to the condition than men, and it is said to be easily acquired by highly nervous people. Downey states that sometimes the tendency towards mirror-writing remains latent, as it were, far into adult life, only to manifest itself during states of exceptional fatigue; and it seems that this might reasonably include "psychic shock," which, from the history, seems to appertain to our case.

Sweeney, Hale and Kuh, and Pendred have advanced visual hypotheses to explain mirror-writing, and we think that a similar hypothesis, suitably modified, offers the best explanation of the phenomena noted in our case. We know that objects of the outside world are projected upon the retina as an inverted image, which remains inverted in the visual cortex. Putnam showed that the upper and lower halves of the retina are represented respectively in the upper and lower lips of the calcarine fissure. The re-inversion of the image and its correct interpretation, probably a function of the visuo-psychic centre, is a "learned process" which, according to the evidence that has accumulated, is rapid and takes place very early in life before the child is able to tell others of its difficulties. Tactile and kinæsthetic impressions associate themselves with the visual impressions in this process of learning.

FIG. 4.



Examples of reversal in copying diagrams. The original drawings were made with coloured chalks.

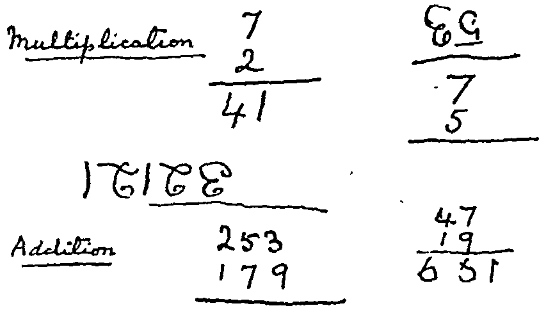
Stern draws attention to inverted drawings of children, and indicates that the very young child is able to recognise a picture upside-down as readily as one right side up. With growth, this ability disappears. Pearson has reported two interesting cases of inverted drawings in children, for which he advances a visual hypothesis. Stratton's well-known experiment showed that erect vision was just a matter of integrating visual data with other sense data and with bodily movement.

The visual theory that is applied to cases of true mirror-writing supposes that vertical relationships are the easiest to rectify, but that there is confusion in the horizontal plane. Thus in the mirror-writer there would be a defective psychological adjustment of the inverted brain image in the lateral plane, whereas vertical relationships would be normally corrected. Orton goes further and suggests that the visual image impinging upon one occipital lobe is the mirrored opposite of the image in the other hemisphere. In the normal subject one of these images becomes suppressed while the other, belonging to the dominant hemisphere, persists. It is suggested that in the mirror-writer supremacy of one hemisphere does not occur, hence there results a constant state to more than ten, it is a common fault with all forms of disordered speech to write down the total sum instead of carrying over one to the next column (Head, vol. ii., p. 333). Thus

$$\begin{array}{r}864\\256\\\hline 10120\end{array}$$

She cannot read ordinary dextrad writing until she has turned it round ("clockwise") and held it upside down. On testing her with different modes of writing it was found that she quite easily read pseudo-mirror-writing, but that she could not read true mirror-writing or inverted writing. When it was pointed out to her that she read and wrote in a strange manner, she insisted stubbornly that: "It is right," or "Us writes proper, don't us." Upon being shown a calendar on the wall she said that the figures were "all right," but that she could not make out the name of the month. When we reversed it the month became intelligible to her, but the figures were "all wrong." The same happened with a time-table. She turned it round "clockwise" to find the names of the stations, but could not then read the time of arrival of the trains. In church she holds her prayer-book upside-down. It has also been observed that when this patient has been tidying up the sister's room, the vases and photos have been put back upon the mantelshelf upside-down, and the pictures and calendars reversed upon the walls.

FIG. 2.



Showing two methods of multiplication and two methods of addition employed by the patient.

This devotion to object-reversal manifests itself in her drawings. In sketching objects from nature, such as a man, a dog, a flower pot (Fig. 3), she draws upside-down when the paper is laid flat before her on the table, but when the paper lies vertical, in front of and parallel with the object, she draws normally. When copying a drawn object that has some definite meaning to her or representing an object with which she is familiar, she will reverse the drawing before attempting to sketch. Then, of course, while the object will actually be upside down, she will draw it the right way up. If, however, what she is asked to copy is a diagram or something which conveys nothing to her so far as orientation is concerned, for instance, a triangle, she does not reverse the paper but copies it upside-down. Colour is affected in the reversal both in the vertical and horizontal relationships (Fig. 4). Her colour appreciation is normal, for she gives correct answers to colour tests. When a sea-painting was shown her, and she was asked which side the lighthouse was, she turned the picture on its head and then said, "On the right." Actually the lighthouse was to her left. Further, when asked to point to the funnels of the ship, which were now upside-down, she indicated a corresponding part of the sea on the top of the picture.

Upon being questioned as to which was the examiner's left hand and her left hand, she made correct answers ("she knew it was her left because she wrote with her other hand"), but when told to look in a mirror and then say which was her left, she invariably mistook her right for her left.

Additional tests were devised to investigate more thoroughly her sense of "spatial appreciation." Two pens, one red, the other yellow, were held one above the other against the wall at a little distance from her. The red pen was above the yellow one, and the question put to her was, "Which colour is on top?" Her answer was: "Yellow." Then the same two pens were held side by side and she was asked which pen was to the left, and she answered that the red was on the left. Actually, the red pen was to the right of the yellow one.

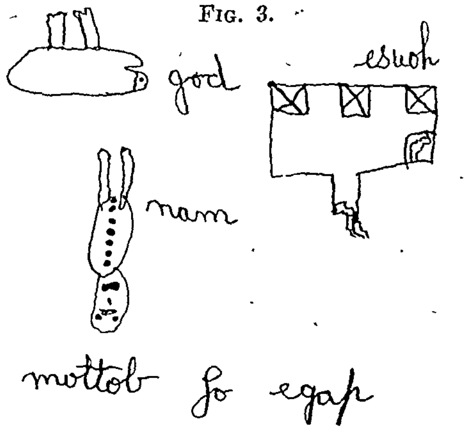
More enlightening were the following tests. The pens were held against the wall cross-wise, the yellow pen a foot in front of the red one. To the inquiry, "Which pen was nearest to her?" she replied: "The red one." Then she was told to feel and see. When she had felt for herself and her mistake was in this way brought home to her she looked bewildered and exclaimed: "Why! the yellow one is nearest!"

A still further test showed the faulty spatial appreciation even more strikingly. One of the pens was held a few feet before her eyes and she was asked, "Was the nib upwards towards the ceiling or downwards towards the floor?" Actually the nib pointed to the floor. Her reply was that the nib pointed upwards, and when she was asked to touch it, expecting to feel the point and encountering only the blunt end, she looked flabbergasted. This test was performed several times, and it was then discovered that she was not in error uniformly but only occasionally. She was asked whether she really saw the pen with the nib pointing to the ceiling, and she said that it had seemed so until she had felt for herself and realised her mistake.

The last two tests are to our mind specially significant in the analysis of her case, showing as they do the discrepancy between her visual and tactile senses.

Her method of spelling is interesting. When requested to spell policeman, she spelt N-A-M-E-C-I-L-O-P; for handkerchief she said F-E-I-H-C-R-E-K-N-E-H; and for California, A-I-N-R-O-F-I-L-A-C—all said quite rapidly, very nearly as quickly as one could spell them forwards. When asked what "Devon" spelt she said, after thinking, "I don't know, sir." Asked what N-O-V-E-D spelt, she said "Devon" at once. Similarly, when asked what Exminster spelt, she looked blank, but when asked "What does R-E-T-S-N-I-M-X-E spell?" (spelling it quite quickly) she said at once—"Exminster."

FIG. 3.



She repeated the alphabet from A to Z in the ordinary manner, though not without making several mistakes in the arrangement of the letters. On being handed cardboard squares corresponding to the letters of the alphabet to arrange in their proper order, this is what she produced:—

Z X Y J W V Q O P S T M N L R U G F K I H E D C B A

When asked to reproduce this effort in writing she y drug intoxication, by fatigue, or by psychic shock, e more highly integrated responses may be thrown t of action and historically simple forms may appear. The general effect of a specific language sturbance is to throw the patient back upon earlier quired and relatively less complex modes of dealing ith the problems that face him, and to limit him a primitive mode of response.

It seems to us, therefore, that "seeing things pside-down" might fairly be regarded as a more rimitive mode of visual response. Our patient adily admits that her sense of sight plays her false hen "checked-up" with her sense of touch.

The psychic disturbance, we believe, is causing her o see objects of the outside world just as they are ast upon the retina unless checked by her intelligence —in other words, unless corrected by reasoning and ommon-sense.

The fact that her speech is now normal, while the ssociated manifestations of reading, writing, and rawing remain perverted, may be explained by he universal law that functions which are the latest, enetically, to develop are the last to recover, seeing hat we know that "Each human being learns to peak and to understand what is said to him during is earliest years; the arts of reading and writing, n the other hand, become possible only after he as already expressed himself fluently in words" Head).

It is notable that our patient does not make mistakes concerning objects that she knows must be "so-and-so" way up. Thus although she may draw —with the paper flat—a person or animal upside down, she interprets them in their natural orientation—i.e., the head on top and the feet below. It is only with reference to objects upon which she can bring to bear no intellectual appreciation that she makes serious errors—e.g., when a pen is held in the air with nib upward no lesson learnt in life, no amount of intelligence, can tell her whether the nib is really pointing upwards or downwards if her vision is playing her tricks, though when asked whether our heads or our feet are on the ground her experience tells her that it must be the feet.

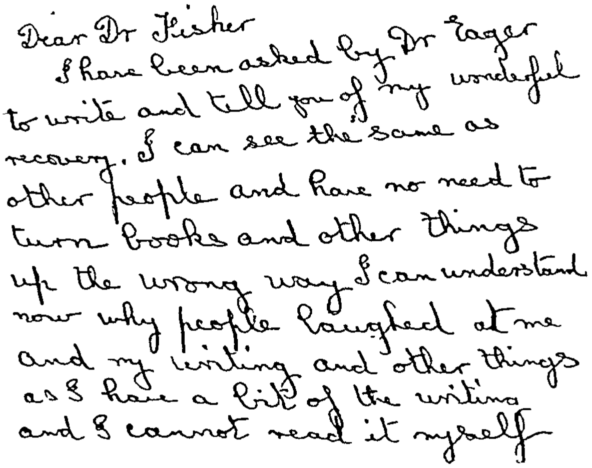
The question whether the loss of speech was a simple hysterical mutism or in the nature of an aphasia seems to resolve itself in favour of the former —with the added explanations and suggestions that we have offered. In contradistinction to our case, who has made a complete recovery from her mutism, Head states quite definitely that in all cases of aphasia that have shown any progress at all, recovery was incomplete and the characteristic disorder was still present to a minor degree. His observation that his non-traumatic cases of aphasia all "progressed" more or less steadily is not without interest for comparison purposes. Our patient shows no want of comprehension of the significance of words or other symbols, as is the way of aphasics; she simply "distorts" them. Furthermore, the aphasic fails to name objects, and experiences more difficulty in reading numbers than words. None of these features are to be found in our case—on the contrary, she reads numerals more easily than words. The backward writing, in certain respects, marches alongside the actions of mirror-writers during hypnosis and in automatic states, and conceivably even the calligraphic displays of mediums during spiritualistic séances.

Inasmuch as all the available evidence points unmistakably to a functional origin, we must perforce class this case in that lazy province of hysteria; at the same time it is the earnest wish of both of us that our attempt at elucidation may do something to stimulate a more lively interest in, and a fuller investigation of, similar problems in the future.

ADDITIONAL NOTE.

After coming to the above-mentioned conclusions, we felt in duty bound to establish our diagnosis by a trial of hypnotherapy. The patient was consequently put under light hypnosis and, whilst in this state, it was suggested to her that after waking she would write, read, and see everything normally. Before leaving the room she was asked to write the operator's name and address on a slip of paper. This was performed, quite freely and without hesitation, in an ordinary manner. The following morning this letter was received (Fig. 5).

FIG. 5.



Dear Dr Fisher
I have been asked by Dr Eager
to write and tell you of my wonderful
recovery. I can see the same as
other people and have no need to
turn books and other things
up the wrong way I can understand
now why people laughed at me
and my writing and other things
as I have a bit of the writing
and I cannot read it myself

There is no doubt now that the diagnosis has been clinched. The patient has been discharged from the hospital, and so far as we can tell at present a complete cure has been effected. She takes a keen delight in writing numerous letters to her relatives and friends "just to show them how well and happy she is."

We desire to acknowledge our indebtedness to Dr. G. W. B. James and to Dr. Macdonald Critchley for the considerable help that they have given us in the preparation of this article; and to the nursing staff of the Devon Mental Hospital for their willing coöperation and assistance.

of doubt as to the correct orientation of objects or of words. Since, in our case, vertical relationships too are confused, it is clear that cerebral dominance can play no part in its ætiology.

The patient's eyesight disability may be of significance. Gray has shown us how faulty eye movements can affect reading, and references in literature to cases of inverted and downward writing disclose a remarkable frequency of defects in the visual apparatus.

Sweeney records a case of a girl of 13 years, of normal intellectual calibre, whose only physical defect was a hypermetropic astigmatism. When wearing suitable glasses her writing was normal, but without them she wrote upside-down and backwards. She drew pictures reversed, and was wont to hold common articles such as pencils upside-down. Like our patient, when asked to spell "carpet" and "house," she said T-E-P-R-A-C and E-S-U-O-H.

Another case mentioned by Hotz is interesting. A girl of 10 became unable to read as the result of taking belladonna by the mouth. She could, however, read quite fluently when she turned the book upside-down. At a distance of 20 feet the Snellen's test-type appeared inverted. When her eyes were completely atropinised (unlike our case, who remained unaffected), and also when a +2·50 lens was placed before her eyes, the inverted vision disappeared.

Through the personal observations made by Bayers we are aware of the occurrence of distortions in the field of vision and reversals in spatial orientation as part of the phenomenology of migraine.

THE POSSIBILITY OF HYSTERIA.

A case recorded by Pick introduces the hysterical factor. A woman who suffered from disseminated sclerosis developed a peculiar visual anomaly which was regarded as hysterical. She complained of seeing people inverted with their heads below. During the stage of inverted vision her reading was affected, and she tended to reverse the order of words and letters.

Our case-history and the nature of the fits strongly suggest the possibility of hysteria—a subconscious wish to remain cared for in institutions rather than to work for a living in the cold, exacting world without. A desire to "hold the stage" and to excite wonder and comment might conceivably be at the bottom of the phenomena. It is a theory that must be accorded respect.

On going into the case-history more thoroughly and collecting information from the patient's married sister and the staff of the infirmary where she was, when the writing peculiarity first manifested itself in 1926, the nature of the "shock" which restored her speech was discovered. It was the witnessing of the precipitate birth of a child in the bathroom of her ward. The sister of that particular ward described the patient as seeming to be always "afraid to be left alone" and "afraid of the dark"; and further added that "she was in the habit of getting into bed the wrong way round"—that is to say, with her head under the clothes at the foot of the bed and her feet where her head ought to be.

She has been watched carefully over a sufficiently long period now, and the consistency of her actions and habits of life seem to negative any possibility of malingering.

With a little practice one of us found that he could read quite well from a newspaper or book held upside-down. It was also discovered that her backward writing could be imitated with fair speed and accuracy. What could not be achieved was to spell as she does. The weak-minded, as we are aware, are often surprisingly talented in certain directions, but even so it would require considerable practice—and an order of intelligence above and beyond what we believe her to possess—to acquire the art of spelling backwards long and difficult words, quickly and correctly, in the relatively short time that elapsed between her discharge from this hospital in 1924 and her admission to the infirmary 18 months later.

Pick's work on "Contrary Actions," referring to cases of speech reversal, has suggested that the writing and reading might conceivably be pseudo deliberate, coupled with a certain amount of negativism. But the patient is not a schizophrenic, nor does she show any signs, so far as we can discover, of schizoid trends or tendencies. She is willing and coöperative rather than negativistic.

The word hysteria is such an indefinite and unsatisfactory entity—everything we do not understand is shot into that psychological ashpit of medicine—and rather than be accused of this unoriginality we would, while recognising the essentially hysterical nature of the case, like to be a little more profound, and we would venture to submit that the disorder is one of faulty spatial discrimination, consequent upon some psychical disturbance in the visual cortex. It is conceivable that if there is some dysfunction of the visual cortex—or of the paths linking it up with the motor centres—reading, writing, and drawing, through faulty perceptual processes, might be misrepresented.

Cases are on record where the ability to reinvert the inverted retinal image has been temporarily lost following cerebral disease or injury. A case in point was recorded to Dr. Schweinitz by Dr. Albert Seitz, of Tenn. This was a 20-year-old youth, who suffered a rather severe head injury and for several weeks thereafter saw everything upside-down. This phenomenon disappeared a month later. A similar case was published in the *New York Medical Journal* of Dec. 18th, 1904. Following an attack of measles an 8-year-old boy saw everything upside-down, and as a consequence had considerable difficulty in orientating himself. On closing his eyes, however, the difficulty disappeared.

Weighing up all the circumstances of the case, we believe that our patient is reading, writing, and drawing "primitively"—in other words, she tends to portray an object as she sees it rather than as training would cause her to perceive it. Our view is that the "fit" which occurred after leaving service was the psychic shock that effected the loss of speech and caused the "learned processes," demanding the effectual coördination of important *centres*, to revert to a childish type, and that the subsequent "shock" whilst in the infirmary was sufficient to restore the former but not the latter.

Head's work on the organic aphasias (which might reasonably be expected, in no small measure, to apply to those of an hysterical nature also) is instructive. Anything which disturbs the free use of language will tend to affect the power of reading and writing to a profound degree. "Articulate speech, the oldest acquisition, racially and individually, exhibits the most specific and particular changes, whilst the recently developed powers of reading and writing are more massively and indifferently affected." Head concludes that in disorders in the use of language there is interference with the use of language *as a whole* and, though certain aspects of it may be disturbed more than others, the defects of speech cannot be expressed in simple terms of audition, articulation, vision, and writing. In other words, there is a dissociation of the highest forms of expression of thought—i.e., of symbolic thinking and expression. We learn from a study of his work that if vigilance is lowered, as it may be by structural injury, by disease, drug intoxication, by fatigue, or by psychic shock, e more highly integrated responses may be thrown t of action and historically simple forms may ppear. The general effect of a specific language sturbance is to throw the patient back upon earlier quired and relatively less complex modes of dealing th the problems that face him, and to limit him a primitive mode of response.

It seems to us, therefore, that "seeing things side-down" might fairly be regarded as a more imitive mode of visual response. Our patient adily admits that her sense of sight plays her false hen "checked-up" with her sense of touch.

The psychic disturbance, we believe, is causing her see objects of the outside world just as they are st upon the retina unless checked by her intelligence -in other words, unless corrected by reasoning and mmon-sense.

The fact that her speech is now normal, while the ssociated manifestations of reading, writing, and rawing remain perverted, may be explained by he universal law that functions which are the latest, enetically, to develop are the last to recover, seeing hat we know that "Each human being learns to peak and to understand what is said to him during is earliest years; the arts of reading and writing, n the other hand, become possible only after he as already expressed himself fluently in words" Head).

It is notable that our patient does not make nistakes concerning objects that she knows must be 'so-and-so" way up. Thus although she may draw —with the paper flat—a person or animal upside down, he interprets them in their natural orientation—i.e., he head on top and the feet below. It is only with eference to objects upon which she can bring to ear no intellectual appreciation that she makes erious errors—e.g., when a pen is held in the air with nib upward no lesson learnt in life, no amount of intelligence, can tell her whether the nib is really pointing upwards or downwards if her vision is playing her tricks, though when asked whether our heads or our feet are on the ground her experience tells her that it must be the feet.

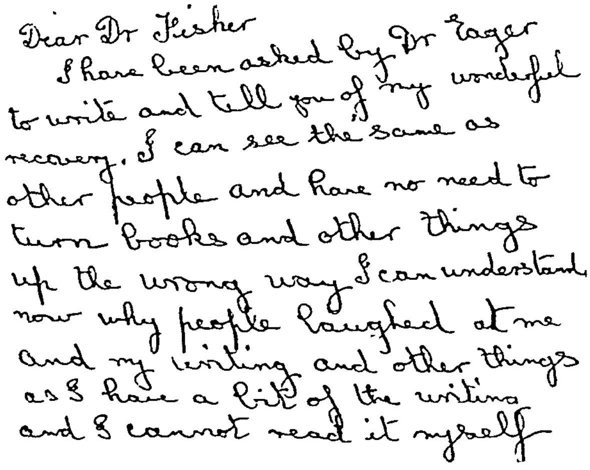
The question whether the loss of speech was a simple hysterical mutism or in the nature of an aphasia seems to resolve itself in favour of the former —with the added explanations and suggestions that we have offered. In contradistinction to our case, who has made a complete recovery from her mutism, Head states quite definitely that in all cases of aphasia that have shown any progress at all, recovery was incomplete and the characteristic disorder was still present to a minor degree. His observation that his non-traumatic cases of aphasia all "progressed" more or less steadily is not without interest for comparison purposes. Our patient shows no want of comprehension of the significance of words or other symbols, as is the way of aphasics; she simply "distorts" them. Furthermore, the aphasic fails to name objects, and experiences more difficulty in reading numbers than words. None of these features are to be found in our case—on the contrary, she reads numerals more easily than words. The backward writing, in certain respects, marches alongside the actions of mirror-writers during hypnosis and in automatic states, and conceivably even the calligraphic displays of mediums during spiritualistic séances.

Inasmuch as all the available evidence points unmistakably to a functional origin, we must perforce class this case in that lazy province of hysteria; at the same time it is the earnest wish of both of us that our attempt at elucidation may do something to stimulate a more lively interest in, and a fuller investigation of, similar problems in the future.

ADDITIONAL NOTE.

After coming to the above-mentioned conclusions, we felt in duty bound to establish our diagnosis by a trial of hypnotherapy. The patient was consequently put under light hypnosis and, whilst in this state, it was suggested to her that after waking she would write, read, and see everything normally. Before leaving the room she was asked to write the operator's name and address on a slip of paper. This was performed, quite freely and without hesitation, in an ordinary manner. The following morning this letter was received (Fig. 5).

FIG. 5.



Dear Dr Fisher
I have been asked by Dr Eager
to write and tell you of my wonderful
recovery. I can see the same as
other people and have no need to
turn books and other things
up the wrong way I can understand
now why people laughed at me
and my writing and other things
as I have a bit of the writing
and I cannot read it myself

There is no doubt now that the diagnosis has been clinched. The patient has been discharged from the hospital, and so far as we can tell at present a complete cure has been effected. She takes a keen delight in writing numerous letters to her relatives and friends "just to show them how well and happy she is."

We desire to acknowledge our indebtedness to Dr. G. W. B. James and to Dr. Macdonald Critchley for the considerable help that they have given us in the preparation of this article; and to the nursing staff of the Devon Mental Hospital for their willing coöperation and assistance.

When wearing suitable glasses her writing was normal, but without them she wrote upside-down and backwards. She drew pictures reversed, and was wont to hold common articles such as pencils upside-down. Like our patient, when asked to spell "carpet" and "house," she said T-E-P-R-A-C and E-S-U-O-H.

Another case mentioned by Hotz is interesting. A girl of 10 became unable to read as the result of taking belladonna by the mouth. She could, however, read quite fluently when she turned the book upside-down. At a distance of 20 feet the Snellen's test-type appeared inverted. When her eyes were completely atropinised (unlike our case, who remained unaffected), and also when a +2·50 lens was placed before her eyes, the inverted vision disappeared.

Through the personal observations made by Bayers we are aware of the occurrence of distortions in the field of vision and reversals in spatial orientation as part of the phenomenology of migraine.

THE POSSIBILITY OF HYSTERIA.

A case recorded by Pick introduces the hysterical factor. A woman who suffered from disseminated sclerosis developed a peculiar visual anomaly which was regarded as hysterical. She complained of seeing people inverted with their heads below. During the stage of inverted vision her reading was affected, and she tended to reverse the order of words and letters.

Our case-history and the nature of the fits strongly suggest the possibility of hysteria—a subconscious wish to remain cared for in institutions rather than to work for a living in the cold, exacting world without. A desire to "hold the stage" and to excite wonder and comment might conceivably be at the bottom of the phenomena. It is a theory that must be accorded respect.

On going into the case-history more thoroughly and collecting information from the patient's married sister and the staff of the infirmary where she was, when the writing peculiarity first manifested itself in 1926, the nature of the "shock" which restored her speech was discovered. It was the witnessing of the precipitate birth of a child in the bathroom of her ward. The sister of that particular ward described the patient as seeming to be always "afraid to be left alone" and "afraid of the dark"; and further added that "she was in the habit of getting into bed the wrong way round"—that is to say, with her head under the clothes at the foot of the bed and her feet where her head ought to be.

She has been watched carefully over a sufficiently long period now, and the consistency of her actions and habits of life seem to negative any possibility of malingering.

With a little practice one of us found that he could read quite well from a newspaper or book held upside-down. It was also discovered that her backward writing could be imitated with fair speed and accuracy. What could not be achieved was to spell as she does. The weak-minded, as we are aware, are often surprisingly talented in certain directions, but even so it would require considerable practice—and an order of intelligence above and beyond what we believe her to possess—to acquire the art of spelling backwards long and difficult words, quickly and correctly, in the relatively short time that elapsed between her discharge from this hospital in 1924 and her admission to the infirmary 18 months later.

Pick's work on "Contrary Actions," referring to cases of speech reversal, has suggested that the writing and reading might conceivably be pseudo deliberate, coupled with a certain amount of negativism. But the patient is not a schizophrenic, nor does she show any signs, so far as we can discover, of schizoid trends or tendencies. She is willing and coöperative rather than negativistic.

The word hysteria is such an indefinite and unsatisfactory entity—everything we do not understand is shot into that psychological ashpit of medicine—and rather than be accused of this unoriginality we would, while recognising the essentially hysterical nature of the case, like to be a little more profound, and we would venture to submit that the disorder is one of faulty spatial discrimination, consequent upon some psychical disturbance in the visual cortex. It is conceivable that if there is some dysfunction of the visual cortex—or of the paths linking it up with the motor centres—reading, writing, and drawing, through faulty perceptual processes, might be misrepresented.

Cases are on record where the ability to reinvert the inverted retinal image has been temporarily lost following cerebral disease or injury. A case in point was recorded to Dr. Schweinitz by Dr. Albert Seitz, of Tenn. This was a 20-year-old youth, who suffered a rather severe head injury and for several weeks thereafter saw everything upside-down. This phenomenon disappeared a month later. A similar case was published in the *New York Medical Journal* of Dec. 18th, 1904. Following an attack of measles an 8-year-old boy saw everything upside-down, and as a consequence had considerable difficulty in orientating himself. On closing his eyes, however, the difficulty disappeared.

Weighing up all the circumstances of the case, we believe that our patient is reading, writing, and drawing "*primitively*"—*in other words*, she tends to portray an object as she sees it rather than as training would cause her to perceive it. Our view is that the "fit" which occurred after leaving service was the psychic shock that effected the loss of speech and caused the "learned processes," demanding the effectual coördination of important centres, to revert to a childish type, and that the subsequent "shock" whilst in the infirmary was sufficient to restore the former but not the latter.

Head's work on the organic aphasias (which might reasonably be expected, in no small measure, to apply to those of an hysterical nature also) is instructive. Anything which disturbs the free use of language will tend to affect the power of reading and writing to a profound degree. "Articulate speech, the oldest acquisition, racially and individually, exhibits the most specific and particular changes, whilst the recently developed powers of reading and writing are more massively and indifferently affected." Head concludes that in disorders in the use of language there is interference with the use of language *as a whole* and, though certain aspects of it may be disturbed more than others, the defects of speech cannot be expressed in simple terms of audition, articulation, vision, and writing. In other words, there is a dissociation of the highest forms of expression of thought—i.e., of symbolic thinking and expression. We learn from a study of his work that if vigilance is lowered, as it may be by structural injury, by disease,

· drug intoxication, by fatigue, or by psychic shock, e more highly integrated responses may be thrown t of action and historically simple forms may ppear. The general effect of a specific language sturbance is to throw the patient back upon earlier quired and relatively less complex modes of dealing th the problems that face him, and to limit him a primitive mode of response.

It seems to us, therefore, that "seeing things side-down" might fairly be regarded as a more imitive mode of visual response. Our patient adily admits that her sense of sight plays her false hen "checked-up" with her sense of touch.

The psychic disturbance, we believe, is causing her see objects of the outside world just as they are st upon the retina unless checked by her intelligence -in other words, unless corrected by reasoning and mmon-sense.

The fact that her speech is now normal, while the ssociated manifestations of reading, writing, and rawing remain perverted, may be explained by he universal law that functions which are the latest, enetically, to develop are the last to recover, seeing hat we know that "Each human being learns to peak and to understand what is said to him during is earliest years; the arts of reading and writing, n the other hand, become possible only after he as already expressed himself fluently in words" Head).

It is notable that our patient does not make nistakes concerning objects that she knows must be 'so-and-so" way up. Thus although she may draw —with the paper flat—a person or animal upside down, he interprets them in their natural orientation—i.e., he head on top and the feet below. It is only with eference to objects upon which she can bring to ear no intellectual appreciation that she makes erious errors—e.g., when a pen is held in the air with nib upward no lesson learnt in life, no amount of intelligence, can tell her whether the nib is really pointing upwards or downwards if her vision is playing her tricks, though when asked whether our heads or our feet are on the ground her experience tells her that it must be the feet.

The question whether the loss of speech was a simple hysterical mutism or in the nature of an aphasia seems to resolve itself in favour of the former —with the added explanations and suggestions that we have offered. In contradistinction to our case, who has made a complete recovery from her mutism, Head states quite definitely that in all cases of aphasia that have shown any progress at all, recovery was incomplete and the characteristic disorder was still present to a minor degree. His observation that his non-traumatic cases of aphasia all "progressed" more or less steadily is not without interest for comparison purposes. Our patient shows no want of comprehension of the significance of words or other symbols, as is the way of aphasics; she simply "distorts" them. Furthermore, the aphasic fails to name objects, and experiences more difficulty in reading numbers than words. None of these features are to be found in our case—on the contrary, she reads numerals more easily than words. The backward writing, in certain respects, marches alongside the actions of mirror-writers during hypnosis and in automatic states, and conceivably even the calligraphic displays of mediums during spiritualistic séances.

THE THERAPEUTIC EFFECTS OF PLASMOQUINE IN PREGNANCY.

By Philip Manson-Bahr, D.S.O., M.D. Camb., F.R.C.P. Lond.,

PHYSICIAN TO THE HOSPITAL FOR TROPICAL DISEASES, LONDON.

The chemical composition and therapeutics of plasmoquine as an efficient antimalarial remedy have recently been much in the public eye, so that its rôle in the routine treatment of the various clinical forms of malaria is now being more widely understood. This subject has been summarised in a recent paper by Prof. W. Schulemann,[1] but there is one aspect of plasmoquine therapy to which few references can be found in the literature—viz., its application in pregnancy. All those who have treated malaria on a large scale will readily recognise the dangers to which pregnant women in the tropics are exposed should they contract a virulent attack. There is a widespread and popular belief, which is fostered by European practitioners in the Far East, that periodical dosage with quinine predisposes to abortion. So strongly is this belief held that in the past I have treated pregnant patients at term who were suffering from advanced malarial cachexia but who had been strictly forbidden by their medical attendants to take quinine in any form in order to check the ravages of the fever. The grounds upon which these beliefs rest appear to be derived more from clinical experience than from scientific evidence. There exists, for instance, very definite proofs that

The pharmacologists, however, are insistent that quinine has a selective action on the uterus. Dixon[5] distinctly states that quinine may bring on labour pains in women who are predisposed to abortion. Sollmann[6] says that quinine stimulates the contraction of the uterus and increases its tone, especially when applied to the excised organ, and the greater the activity and tone of the uterus the more rapid the action of the quinine. It is usually perceptible 40 minutes after oral administration.

From the molecular structure of plasmoquine it is reasonable to infer that its therapeutic action upon the uterine muscle would be different from that of quinine, and it has been found as the result of experiments on animals carried out in the Bayer Works in Elberfeld * that in concentrations of 1 : 50,000 to 1 : 100,000 plasmoquine has no influence upon the isolated uterus of guinea-pigs. In situ, the uterus does not react to an intravenous injection of 0·05 mg. per kg. body-weight, and contraction is only observed after an injection of twenty times that amount. This, however, is thought to be due to a transitory decrease in blood pressure and not to any specific action.

Six papers have already appeared upon the action of plasmoquine in pregnancy. Jansen[7] successfully treated a pregnant woman suffering from malaria with plasmoquine 0·02 g. (gr. $\frac{1}{3}$), twice daily, as well as with stovarsol (interval treatment with pauses of four days). Nissenbaum[8] was equally successful in a seven months' pregnant malaria patient who had previously been unsuccessfully treated with quinine for seven months. Plasmoquine, 0·06 g. (gr 1 daily, for five courses, was given in this instance ɔer cent.; numerous B.T. schizonts and gametocytes. moquine-compound tablets, commencing with 0·03 g. 0·375 g. of quinine. and increasing to 0·09 g. plasmoɪe plus 1·125 g. quinine. Male child born two days after ation of first week of treatment. During puerperium moquine compound, two tablets twice daily (0 04 g. moquine plus 0·5 g. quinine). for three separate weeks ı an interval of three days between each course.

ase 2.—Benign tertian infection, aged 31. from Assam. ı August 16th, 1929, arrived in England Dec. 22nd, ; frequent attacks of malaria not reacting to quinine. ee months pregnant; spleen enlarged; slight anæmia; noglobin, 80 per cent.; B.T. parasites found in India. rse of plasmoquine compound given as in Case 1; maxim dose 0·04 g. plasmoquine daily. Male child born at term; no relapses during parturition. Reported two rs later; no return of malaria.

ase 3.—Subtertian infection. aged 33, from Tanganyika ritory; arrived in England May 17th, 1931; admitted Hospital for Tropical Diseases on May 31st. Temperae, 103° F. First attack of malaria; seven months gnant. Spleen not palpable; slight anæmia; hæmobin, 70 per cent.; many subtertian rings found. Treated above with 0 03 to 0·04 g. of plasmoquine daily. Female ld born August 4th, 1931, and died three days later in vulsions. No further relapses of malaria.

ase 4.—Subtertian infection. aged 29, from Nigeria; ived March, 1931, when three months pregnant. Admitted Hospital for Tropical Diseases on June 24th, 1931. Had en suffering from relapses of subtertian malaria every en to ten days since arrival in England. Spleen not lpable; hæmoglobin, 70 per cent.; numerous subtertian gs in blood; albumin and urobilin present in urine. tient in critical condition. Quinine caused cramp-like lings akin to premenstrual pains, and had therefore not en persisted with. Plasmoquine well tolerated (four blets a day 0·04 g. of plasmoquine plus 0·5 g. of quinine). ly in hospital one week; great improvement in clinical ndition. Two slight relapses reported. Male child born d of September. Seen by her local doctor Feb., 1932; further relapses since birth of child.

Case 5.—Quartan infection, aged 27, from Southern geria; arrived in England May 1st, 1931; four months egnant. Spleen enlarged; anæmia marked; hæmobin, 65 per cent.; temperature, 103° F.; numerous pical half-grown quartan parasites present. Treatment plasmoquine compound, four tablets daily, as outlined ove. Male child born at full term; no further attacks fever.

My experience of this subject is naturally someat limited on account of the scarcity of clinical aterial, but it can be stated from the above facts at the combination of plasmoquine and quinine pears to be well tolerated by pregnant women. d is unattended by danger either to the mother or e child in all three clinical varieties of malaria. consider that the appropriate therapeutic dose of asmoquine compound in this condition is four blets of the standarised product daily (0·04 g. of asmoquine plus 0·5 g. of quinine sulphate) for e separate weeks with a pause of three days' erval between each weekly course.

Clinical and Laboratory Notes

TWO CASES OF GLANDULAR FEVER IN A FAMILY.

By Alan Moncrieff, M.D., M.R.C.P. Lond.,

PHYSICIAN FOR DISEASES OF CHILDREN, BOLINGBROKE HOSPITAL, WANDSWORTH.

According to H. L. Tidy,[1] writing in 1930, two cases of glandular fever in a family are unusual, although not unknown. Because of this and because the two following cases throw some light upon the incubation period of the disorder they are here put on record.

Case 1.—A. B., aged 7 years, was sent to the children's out-patient department of the Bolingbroke Hospital, Wandsworth, on Feb. 16th, 1932, for fever and swelling of her glands. The history given was that on Feb. 5th the glandular enlargement "behind the ears" was first noticed and on the same day a fleeting rash, described by the mother as like a "blush" over the face and trunk, appeared. Slight fever occurred and persisted and the glandular swelling showed no sign of subsiding during the next few days. For the four or five days before her coming to hospital she had complained of slight headache and loss of appetite, but had otherwise not seemed ill and there was no sore-throat. When seen on Feb. 16th she had a temperature of 99° F. There were many small lymphatic glands easily felt in the posterior triangles of each side of the neck, in both axillæ and in both groins, and the left epitrochlear gland was easily felt. The throat was normal in appearance. The spleen was not felt but the liver was easily felt for a depth of about one inch below the costal margin. A white cell count showed 11,400 cells per c.mm. No differential count was done.

One week later the child returned to the out-patient department having stayed in bed at home. Her temperature was still raised, being 99 2° F., and the glandular enlargement was the same as before. She was admitted to hospital where a blood count was as follows: red cells, 6,100,000 per c.mm.; hæmoglobin, 112 per cent.; white cells, 13,100 per c.mm.; with the following differential count: polymorphonuclears, 52 per cent.; eosinophils, 0·34 per cent.; hyalines, 2·34 per cent.; lymphocytes (large and small), 45·34 per cent. The child remained in hospital for about ten days during which time there was no rise in temperature and the glands rapidly subsided.

Case 2.—Meanwhile on March 1st, 1932, her younger brother was sent up to the out-patient department for the same complaint. B. B. was 5½ years old and on Feb. 26th swellings in his neck had been noticed. There had been no rash in his case. On examination there was a slight rise in temperature to 98·8° F., but the boy looked and felt perfectly well. There were numerous shotty glands in the posterior triangles of the neck, in the left axilla and both groins, and the left epitrochlear gland was enlarged. The tip of the spleen could just be felt, but there was no enlargement of the liver. The throat appeared normal. A blood count showed: red cells, 5,800,000 per c.mm.; hæmoglobin, 98 per cent.; white cells, 13,800 per c.mm.; with a differential count as follows: polymorphonuclears, 45 67 per cent.; eosinophils, 2 per cent.; basophils, 0·34 per cent.; large hyalines, 4·34 per cent.; and lymphocytes (large and small), 47·67 per cent. The child was sent home to bed for a few days, and in a letter from Dr. Patrick Purcell, under whose care both children were at home, dated March 20th, it was stated they had both quite recovered.

These cases present several points of interest. The diagnosis in the first case could not really be definitely established until the brother became also affected, and if the brother had come to hospital as an isolated case it would have been equally difficult to be dogmatic about the diagnosis of glandular fever although it appeared to be the most likely one. The enlargement of the epitrochlear gland in both children is a point noted by other observers as common in glandular fever, while the slight predominance of glandular enlargement on the left side of the body is another small point also previously noted. The blood counts do not show a very marked divergence

THE THERAPEUTIC EFFECTS OF PLASMOQUINE IN PREGNANCY.

BY PHILIP MANSON-BAHR, D.S.O., M.D. CAMB.,
F.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL FOR TROPICAL DISEASES, LONDON.

THE chemical composition and therapeutics of plasmoquine as an efficient antimalarial remedy have recently been much in the public eye, so that its rôle in the routine treatment of the various clinical forms of malaria is now being more widely understood. This subject has been summarised in a recent paper by Prof. W. Schulemann,[1] but there is one aspect of plasmoquine therapy to which few references can be found in the literature—viz., its application in pregnancy. All those who have treated malaria on a large scale will readily recognise the dangers to which pregnant women in the tropics are exposed should they contract a virulent attack. There is a widespread and popular belief, which is fostered by European practitioners in the Far East, that periodical dosage with quinine predisposes to abortion. So strongly is this belief held that in the past I have treated pregnant patients at term who were suffering from advanced malarial cachexia but who had been strictly forbidden by their medical attendants to take quinine in any form in order to check the ravages of the fever. The grounds upon which these beliefs rest appear to be derived more from clinical experience than from scientific evidence. There exists, for instance, very definite proofs that malaria per se may be the cause of abortion, and that extensive infection of the placenta with the subtertian malaria parasite may result in the death of the child and premature expulsion. Blacklock and Gordon[2] have stated that 38 per cent. of placentæ from West African native women examined in Freetown contained large numbers of *Plasmodium falciparum*, and that 25 per cent. of children born of mothers whose placentæ were infected died within seven days. All are agreed that labour tends to light up latent malaria, for the malaria parasite may be present in the woman's blood or in her placenta, lying in a dormant condition, so that the first typical pyrexial malaria attacks may make themselves evident only in the throes of labour.

Theobald[3] has summarised the evidence in a paper read in 1930 as follows: Quinine is used in obstetrics (1) to induce labour, and (2) to render labour pains more effectual—i.e., in uterine inertia. For the induction of labour with quinine the routine adopted is to give three or four doses of quinine in ten-grain doses at three-hourly intervals, two ounces of castor oil being given after the third dose. Out of 52 cases there were only six failures to induce labour. There is no doubt that quinine does increase the severity of the uterine contractions, but in Theobald's experience these contractions are not sufficient to induce labour until the patient is at term or close to it. The fact is that quinine is valueless to the obstetrician as an abortifacient.

There appears to be no evidence that quinine, when given in the generally accepted therapeutic doses, has any effect upon the well-being of the fœtus, for Dilling and Gemmell[4] have collected a series of 9765 cases in which quinine was used to induce labour, and have concluded that in only eight stillbirths can this drug have been responsible. This then is the evidence of the obstetrician.

The pharmacologists, however, are insistent that quinine has a selective action on the uterus. Dixon[5] distinctly states that quinine may bring on labour pains in women who are predisposed to abortion. Sollmann[6] says that quinine stimulates the contraction of the uterus and increases its tone, especially when applied to the excised organ, and the greater the activity and tone of the uterus the more rapid the action of the quinine. It is usually perceptible 40 minutes after oral administration.

From the molecular structure of plasmoquine it is reasonable to infer that its therapeutic action upon the uterine muscle would be different from that of quinine, and it has been found as the result of experiments on animals carried out in the Bayer Works in Elberfeld * that in concentrations of 1 : 50,000 to 1 : 100,000 plasmoquine has no influence upon the isolated uterus of guinea-pigs. In situ, the uterus does not react to an intravenous injection of 0·05 mg. per kg. body-weight, and contraction is only observed after an injection of twenty times that amount. This, however, is thought to be due to a transitory decrease in blood pressure and not to any specific action.

Six papers have already appeared upon the action of plasmoquine in pregnancy. Jansen[7] successfully treated a pregnant woman suffering from malaria with plasmoquine 0·02 g. (gr. $\frac{1}{3}$), twice daily, as well as with stovarsol (interval treatment with pauses of four days). Nissenbaum[8] was equally successful in a seven months' pregnant malaria patient who had previously been unsuccessfully treated with quinine for seven months. Plasmoquine, 0·06 g. (gr. 1) daily, for five courses, was given in this instance with the object of preventing abortion. Majumdar[9] treated a group of malaria patients, amongst whom were two pregnant women, with similar doses of plasmoquine, and found that the drug did not cause uterine contractions. He considers that plasmoquine has no detrimental action on the non-striated musculature and the pregnant uterus. Thakkar[10] treated a multipara in the fifth month of pregnancy with 0·06 g. daily, and found it well tolerated. In four other cases in the third and eighth months of pregnancy success was also achieved. Frank[11] in Palestine especially recommends plasmoquine in pregnant women, for he successfully treated a pregnant woman and brought her to full term by combined plasmoquine and quinine treatment. He considers it important, because in this case a tendency to abortion undoubtedly existed. Epstein[12] says that in therapeutic doses plasmoquine has no effect the uterus. It follows that the drug can be conside ed safer to employ than quinine when treating pregn t women suffering from malaria.

SOME CASE RECORDS.

Since 1928 I have treated five cases of pregnant women suffering from all three malaria infection, from the third to the of pregnancy. All have been given p compound in the usually accepted therap over a period of five separate weeks. The r been most satisfactory. My records show further relapse has occurred either during or postpartum. The children have been b term, and the only stillbirth was due to ir tion.

CASE 1.—Benign tertian infection, aged 34, an the Federated Malay States on Sept. 5th, 1928; attacks of fever since March, 1928, uncontrolled by eight months pregnant; enlarged spleen;

Clinical and Laboratory Notes

TWO CASES OF GLANDULAR FEVER IN A FAMILY.

By ALAN MONCRIEFF, M.D., M.R.C.P. LOND.,
PHYSICIAN FOR DISEASES OF CHILDREN, BOLINGBROKE HOSPITAL, WANDSWORTH.

ACCORDING to H. L. Tidy,[1] writing in 1930, two cases of glandular fever in a family are unusual, although not unknown. Because of this and because the two following cases throw some light upon the incubation period of the disorder they are here put on record.

CASE 1.—A. B., aged 7 years, was sent to the children's out-patient department of the Bolingbroke Hospital, Wandsworth, on Feb. 16th, 1932, for fever and swelling of her glands. The history given was that on Feb. 5th the glandular enlargement "behind the ears" was first noticed and on the same day a fleeting rash, described by the mother as like a "blush" over the face and trunk, appeared. Slight fever occurred and persisted and the glandular swelling showed no sign of subsiding during the next few days. For the four or five days before her coming to hospital she had complained of slight headache and loss of appetite, but had otherwise not seemed ill and there was no sore-throat. When seen on Feb. 16th she had a temperature of 99° F. There were many small lymphatic glands easily felt in the posterior triangles of each side of the neck, in both axillæ and in both groins, and the left epitrochlear gland was easily felt. The throat was normal in appearance. The spleen was not felt but the liver was easily felt for a depth of about one inch below the costal margin. A white cell count showed 11,400 cells per c.mm. No differential count was done.

One week later the child returned to the out-patient department having stayed in bed at home. Her temperature was still raised, being 99·2° F., and the glandular enlargement was the same as before. She was admitted to hospital where a blood count was as follows: red cells, 6,100,000 per c.mm.; hæmoglobin, 112 per cent.; white cells, 13,100 per c.mm.; with the following differential count: polymorphonuclears, 52 per cent.; eosinophils, 0·34 per cent.; hyalines, 2·34 per cent.; lymphocytes (large and small), 45·34 per cent. The child remained in hospital for about ten days during which time there was no rise in temperature and the glands rapidly subsided.

CASE 2.—Meanwhile on March 1st, 1932, her younger brother was sent up to the out-patient department for the same complaint. B. B. was 5½ years old and on Feb. 26th swellings in his neck had been noticed. There had been no rash in his case. On examination there was a slight rise in temperature to 98·8° F., but the boy looked and felt perfectly well. There were numerous shotty glands in the posterior triangles of the neck, in the left axilla and both groins, and the left epitrochlear gland was enlarged. The tip of the spleen could just be felt, but there was no enlargement of the liver. The throat appeared normal. A blood count showed: red cells, 5,800,000 per c.mm.; hæmoglobin, 98 per cent.; white cells, 13,800 per c.mm.; with a differential count as follows: polymorphonuclears, 45·67 per cent.; eosinophils, 2 per cent.; basophils, 0·34 per cent.; large hyalines, 4·34 per cent.; and lymphocytes (large and small), 47·67 per cent. The child was sent home to bed for a few days, and in a letter from Dr. Patrick Purcell, under whose care both children were at home, dated March 20th, it was stated they had both quite recovered.

These cases present several points of interest. The diagnosis in the first case could not really be definitely established until the brother became also affected, and if the brother had come to hospital as an isolated case it would have been equally difficult to be dogmatic about the diagnosis of glandular fever although it appeared to be the most likely one. The enlargement of the epitrochlear gland in both children is a point noted by other observers as common in glandular fever, while the slight predominance of glandular enlargement on the left side of the body is another small point also previously noted. The blood counts do not show a very marked divergence from the normal of childhood, and although both the total number of white cells (over 13,000 per c.mm.) in each case, and the relative proportion of lymphocytes are slightly raised, the evidence of the blood picture alone is scarcely sufficient to establish a definite diagnosis. This serves to illustrate the point that a single normal blood count cannot be used to exclude the diagnosis of glandular fever. Possibly if blood counts had been done at different periods of the disease more striking evidence of lymphocytosis or mononucleosis would have been found.

The occurrence of a rash in the case of the girl is most unusual and it is to be regretted that it was not seen by a competent observer as the doctor was not called in until five days after it had disappeared. Tidy,[2] reviewing the 1930 epidemic, has stated that none of the children had rashes in the cases seen by him, and partly on this he has elaborated his thesis of the differing types of the disease in children and adults. The longer duration of the fever in the case of the girl, nearly four weeks in all, will fit better with Tidy's adult type than with the usual type in childhood with no rash.

INCUBATION PERIOD.

The last point of interest, and the main reason for this brief communication, is the incubation period in the case of the boy. His illness appeared to begin with swelling of the glands 21 days after his sister had first exhibited symptoms. It is impossible to argue from this that the incubation was three weeks because the exact date of "exposure" is unknown beyond the fact that he was exposed to infection during most of this period. No other cases were recognised among the friends or relatives of these two children so that it is permissible to conclude that the boy caught his glandular fever from his sister. The incubation period of the disease is usually given as from five to ten days (Tidy and Morley [3]), five to twelve days (Tidy [1]), five to nine days (Baldridge,[4] Hasselmann [5]), or seven to eight days (Glanzmann [6]), to quote some of the authoritative pronouncements on this subject. All authors are agreed, however, that the period may be longer up to two or three weeks. Krestin [7] has recorded an example during the 1930 epidemic in this country where a man developed the disease 14 days after his wife, and in an epidemic at a school in 1923 Tidy and Daniel [8] found an incubation period of ten to twelve days. On the other hand, Glanzmann [6] remarks in his comprehensive monograph that where more than one case occurs in a family the interval between the onset of symptoms is usually five days, and in the 1930 epidemic Tidy [2] describes two brothers affected by this disorder with six days between the onsets. The cases here described appear to have an exceptionally long interval between the beginning of symptoms.

I am indebted to Dr. S. E. Levitt for the blood counts in these two cases, and to Dr. Patrick Purcell, of Battersea, for the history before and after their coming to hospital.

MALIGNANT GLANDS OF GROIN TREATED WITH RADIUM.

By WINIFRED F. BUCKLEY, O.B.E., M.R.C.S.ENG.

THE interest of the following case lies in the fact that the primary focus of a squamous carcinoma which had invaded lymphatic glands and was apparently cured by the application of radium, remained undiscovered.

The patient, aged 65, first noticed a small lump in the right groin in the spring of 1930. She saw a doctor in April, who told her she had an enlarged gland. It was not inflamed but grew slowly, and in November she had an attack of abdominal pain with "*stoppage*" for two or three days. A consultant was called in, and her relatives were informed that she had malignant disease of the intestine, with secondary growth in the gland, and that nothing could be done except to relieve symptoms as they arose. She was losing weight rather rapidly. The gland continued to grow, became *inflamed*, and *it* became painful to flex the thigh. A lump in the left groin was first noticed shortly after Christmas, 1930, when a mass appeared in the upper part of the right thigh.

When I was asked to see her in April, 1931, she had a malignant growth in the right groin, just above Poupart's *ligament, the size of a tangerine orange.* It was inflamed and discharging; it involved the skin and was partly fixed to the deeper structures. There was an enlarged gland in the left groin, the size of a plover's egg, firm, discrete, and movable. Below Poupart, on the right side, was a mass of glands near the femoral vessels, about 3½ in. *by 2 in. in diameter.* There had been no recurrence of intestinal trouble, and apart from slight tenderness in the epigastrium, nothing could be felt in the abdomen. No primary focus was discovered in the cervix or body of the uterus, which was small and senile, or in the vagina, vulva, or rectum.

I asked Miss L. Martindale to see her, and it was decided to admit her to the Marie Curie Hospital for treatment. The gland in the left groin was removed for pathological examination and reported to be a definite squamous carcinoma; radium needles were introduced below the wound and were also inserted into and below the growth on the right side. The *patient returned* home and was readmitted in June and July for radium plaques to the right thigh. In August, as her general condition had so much improved, needles were inserted into the growth below Poupart. In three months from the first treatment the growth had entirely disappeared and is now replaced by a flat scar, pale in colour, and surrounded by pigmented skin. There is a depressed scar in the left groin, and no recurrence of growth. The mass below Poupart has disappeared. The patient, who was emaciated and very frail when first seen, put on a stone in weight after treatment and is now active and well.

The problem is: Where did this squamous carcinoma originate? If there is no central focus, why were glands on both sides affected? The primary focus cannot be intestinal, it cannot have originated in lymphoid tissue. Did it originate from a cell rest of other tissue in the gland, or from the deeper layers of the skin and penetrate the gland?

I am indebted to Miss Martindale and the Marie Curie Hospital for permission to publish this case.

London, W.

A SWEEPSTAKE COT.—The winner of a large sum in the recent Irish sweepstake has given £500 for the endowment of a cot in the West Herts Hospital. It is to be named after her child who was in the hospital many years ago.

MEDICAL STAFF OF HEREFORD HOSPITAL.—By the narrow majority of 30 to 37 the annual meeting of the Herefordshire General Hospital decided to delete the following rule: "No partner of a *member* of the general staff shall be eligible for election to, or remain a member of that staff." The argument in favour of the alteration was that the rule limited the discretion of the governors in selecting members of the honorary staff, but the majority of the medical staff were opposed to it.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE.

SECTION OF PHYSICAL MEDICINE.

AT a meeting of this section held on April 16th. he chair was taken by Dr. F. G. THOMSON. President. nd Sir ROBERT JONES read a paper on

Manipulation as a Therapeutic Measure.

lanipulation, he said, must form an important part f the armamentarium of the orthopædic surgeon. nd be only one of the many activities on which e was engaged. It was essential to consider the reventive side: in many cases manipulations were he essential sequelæ to faulty diagnosis and faulty reatment. Text-books were very inadequate on his important subject, and mistakes were frequent. t might be assumed that a stiff joint was due to dhesions, either within or without, or both, comlicating some other condition or forming the sole ause of stiffness. The division into intra-articular nd extra-articular adhesions was useful, but to a arge extent artificial.

Adhesions related to injuries required more radical reatment than those due to inflammatory lesions: he former called for active, passive, or even forcible movement and the latter for rest. Unqualified practitioners often—and even the qualified sometimes—failed to make this differentiation; the osteopath tended to break down arthritic adhesions, while the medical man allowed traumatic adhesions to become cicatricial through wrongly prescribed rest. The following point was useful in differential diagnosis: a joint of which the movement was limited in all directions was—or had been—the seat of arthritis; a joint of which the movement was limited in certain directions only, and normal in others, was not arthritic. It was essential to know the normal movements of which each joint was capable. Stiffness rapidly following trauma (excluding fractures and displacements) suggested adhesions; the same was true of a superficial tenderness over a limited area, either on movement or on pressure, or on both. An arthritic joint was usually warmer over its whole surface than a joint with adhesions. Muscular wasting in an inflamed joint was in excess of that caused by mere desuetude; this was not the case in adhesions.

Radiography was invaluable, and should be used even in the apparently simplest case. The radiologist's reading of the film should, moreover, be welcomed. A slightly bent knee, negative to radiology, always suggested a displaced semilunar cartilage. An inflamed post-patellar pad could be felt enlarged when compared with the opposite side. A villous synovial membrane could be diagnosed by palpation and confirmed by finding thickened synovial fluid on aspiration. A bony block to full extension, confirmed by X rays, was characteristic of a displaced tibial spine. A knee which could be voluntarily fully extended, painful and of long standing, negative to X rays, was almost always affected by adhesions. A stiff, flexed knee, with limited movement, should be the subject of careful consideration before deciding on any form of manipulation.

A movable joint was not necessarily the best functional result, especially in tuberculosis. The movement naturally acquired after many years of ankylosis was often the patient's undoing; for this reason the speaker had advocated early bony ankylosis. In certain septic or rheumatic cases of arthritis the formation of adhesions might be prevented by allowing movement as soon as this caused no pain. Before movements were allowed, a precise diagnosis must be made. Torn ligaments or muscles must be protected. Gentle massage checked lymph effusion, relieved pain, and allowed early recovery of tissues, but should be dissociated from movement. A pressure pad was useful if a ligament was torn; pressure limited effusion. In the stage of effusion no painful movements should be allowed lest ligaments stretch.

If a child's joint was fixed in a normal position for a short time no more harm would result than a brief period of stiffness; this did not apply to the elderly. A joint should never be fixed hyperextended. The value of training muscles to contract without producing movement ought to be fully realised as these movements prevented adhesions within the muscle sheath. Movements should be practised in all joints having muscular attachments associated with the fixed joint.

Arthritic joints must not be mobilised until X ray plates showed the cessation of destructive processes. If an increase in movement followed cessation of fixation, gentle active movements without weight-bearing should be relied on for treatment. The experiment must be carefully watched. Active movements were preferable to passive whenever they were possible and effective; they needed hardly any supervision, while passive movements must be very carefully supervised. Masseuses seldom realised that it was only necessary to put a joint through its movements once a day.

FORCIBLE MOVEMENTS.

Recent lesions might be broken down under gas and oxygen, but a more complete anæsthetic was required for firmer bands, as complete relaxation was essential. The movements of the healthy joint under operation should be compared with those of the affected side and the joint should usually be put through its whole range at one operation. The patient should recover consciousness with his joint in full over-correction.

Sir Robert Jones then described his manipulation of a knee-joint, and of a shoulder in the elderly. After-treatment, he said, should begin immediately. An effusion could be ignored unless associated with a decreasing range of movement. Even pain did not indicate rest if the range increased with movement. Pain continuing after the movement was finished was a danger signal. In myositis ossificans rest was imperative until the deposition of bone was ended; even massage was contra-indicated. Correct alignment was of more value than end-to-end apposition in fractures of the long bones. Bones of the lower limb must be given longer to heal than text-books allowed, on account of weight-bearing. Recent fractures should not be mobilised until reduction was complete. Alternating manipulation and fixation were used for congenital deformities such as club-foot and congenital dislocation of the hip.

DISCUSSION.

Dr. J. B. MENNELL spoke of the great influence Sir Robert Jones had exerted, and recalled the history of orthopædic work in the war and the formation of the Shepherd's Bush Hospital. He said that if the range of movement were seriously limited he preferred

lestroyed. Dr. Brown found it difficult to accept heory of very early incest impulses put forward r. Jones, though he had been able to verify the ral theory that nightmares were related to ssed sexual impulses. The intense stimulation he emotion of fear in a repressed form could in many of these phenomena. Fear was more amental than sex in human life. Over-stimulation le nervous system by general fear aroused strong al feelings. He would not say that these early incest encies were not present; but they were difficult icit, and it seemed unnecessary to invoke them.

r ROBERT ARMSTRONG-JONES described personal riences of nightmare, and confessed his inability egard them as wish-fulfilments. He regarded n as recalls of former fear-stimuli by association. sex motive seemed to him fantastic, and he ared his belief in vitalism, particularly hormism. experience had not suggested that dream inter- ation helped the treatment of the insane. He tested against the present tendency to regard all ital abnormality as due to disorder of the endocrine ıds.

r. JONES, in reply, said that terror dreams were mmon but typical nightmares were uncommon.

he CHAIRMAN, on behalf of Dr. B. FARRINGTON, d a paper on the Preface of the De Humani Fabrica Vesalius. In these prefatory declarations, he l, the great master spoke from the zenith of his eer, fully conscious of his worth. Dr. Farrington l translated the declarations into modern language, l the translation would be published in the ceedings. He read extracts from Dr. Farrington's rk.

CTION OF OBSTETRICS AND GYNÆCOLOGY.

At a meeting of this section on April 15th with . VICTOR BONNEY, the President, in the chair, a per on

Ectopic Gestation

s read by Prof. H. LEITH MURRAY (Liverpool). presented the results of an experience of 146 secutive cases, and was written expressly from the ndpoint of the gynæcologist as opposed to that of general surgeon. The attitude of the latter, n faced with an urgent abdominal crisis, usually him to carry out exploratory laparotomy, and ften missed the finer points of diagnosis. The s of 146 cases, on which he had himself operated, ined no ovarian pregnancies, no bilateral tubal ancies, and no interstitial or cornual pregnancies; were there any obvious tubal abnormalities or suggestions of external or internal migration of ovum. In the whole series there had only been desperate emergencies, and none showed primary peritoneal rupture. More than half the cases moderately serious, and usually with somewhat istories of pain and bleeding, with considerable dism. Two patients' first complaint was that were sterile. He always operated on making diagnosis, for he mistrusted tubal gestation and in ry cases the diagnosis should be easy. It be suspected in all cases with a short history ting pregnancy and with the symptom of pain proportion to that found in early abortion. times he had operated and found a condition was an acute exacerbation of old appendage , with peritoneal shock due to leakage. Two s died, and both had a long history of mis- is, with much anæmia and intraperitoneal g. The average age of all the patients was 84 cases the condition was on the right side, in 62 on the left; in 103 cases the pregnancy was ampullar, 40 being isthmial.

The possible terminations of tubal gestation included spontaneous cure, rupture, or continued growth. He favoured operation in every case diagnosed as tubal gestation; it gave immediate relief of symptoms and a rapid convalescence. In 53 of the 103 ampullary cases the fœtus was almost extruded, or seemed likely to be. In 15 of the 40 isthmial cases it bulged outwards and sideways, and there seemed but slight chance of extrusion into the lumen of the tube. He had histological evidence of absorption in situ in only one case. He had met with only 11 cases of primary intratubal rupture, with the fœtus varying between a quarter of an inch and one and a half inches long, and 92 per cent. of his cases showed primary intratubal rupture without further complication. In 71 out of 94 cases there was evidence of considerable round-celled deposit; in 23 there was none. He had no case of primary extratubal rupture; and in none of the cases of tubal pregnancy was there clear evidence of primary intraperitoneal rupture. There was evidence that spontaneous cure might frequently occur.

Prof. Murray then proceeded to discuss the ætiology of tubal pregnancy. Twenty-six of his cases showed absolute sterility; 24 showed one-child fertility with an interval ranging between 5 and 14 years. In studying the likelihood of endosalpingitis as a cause of tubal gestation, he submitted that mild trouble, with maintenance of the patency of the tube, was more likely to be a cause than severe infection. There were six cases of recurrent tubal gestation. The causes of tubal gestation must be of very mild character, and so were liable to be overlooked. If appendicitis was a factor, it did not follow necessarily that its effects would be in the right tube alone. Of the 133 cases of tubal pregnancy, 50 were associated with reduced fertility, and in 42 of the 50 there was evidence of old peritoneal infection. Fifty showed evidence of old pelvic inflammatory infection. He asked that workers in this field would make a more careful statement of what they found in the vermiform appendix in cases of tubal gestation.

A paper by Prof. LEITH MURRAY and Dr. A. A. GEMMELL (Liverpool) was read by the latter on two cases of

SIMULTANEOUS INTRA- AND EXTRA-UTERINE PREGNANCY

of which they said 213 cases had been recorded.

The first of the two patients was a woman, aged 31, who had been married four and a half years. She had one normal labour in 1925 and a miscarriage in 1927. In 1919 a growth was removed from her breast, and in 1927 she had cholecystectomy. The last menstrual period was at the end of October, 1928, and early in 1928 she had a profuse vaginal hæmorrhage which lasted a week. She was taken into hospital in the following January, having had pain in the left iliac fossa, radiating to the right; for six weeks defæcation had been painful. In the previous month she had had acute abdominal pain with violent vomiting. There was a mobile swelling in the hypogastrium, extending three fingers-breadth above the symphysis pubis. The cervix was soft and mobile; the body of the uterus was large and its consistence suggested pregnancy. On the left side was a tender swelling attached to the uterus. Abdominal section was performed on Jan. 15th. Dark blood could be seen through the peritoneum, and as soon as the peritoneum was excised a 12-weeks' fœtus presented. Because of the amount of handling of the pelvic organs it was decided to empty the uterus, which also contained a fœtus. A cystic portion of the right ovary was incised, but it did not contain a corpus luteum. Uninterrupted recovery followed.

The second woman was aged 35 and had had two children, the second nine months ago. Menstruation was regular.

a two-stage operation. He asked if Sir Robert believed in the "locking" of a joint. If a joint could not "lock" the osteopathic manipulation fell to the ground unless adhesions had formed.

Dr. C. B. **Heald** urged Sir Robert Jones to add further practical instructions in his printed paper. He had had personal experience of sudden "locking," relieved immediately and completely by manipulation.

Mr. J. **McMurray** asked Sir Robert Jones if he believed that any manipulation could put right a stretched and displaced cartilage.

Dr. **Murray Levick** described a personal experience of "locking" in the back cured by a sudden voluntary jerk associated with an "electric thrill," obviously due to disturbance of a pair of spinal nerves. He asked how Sir Robert would treat badly strained shoulder-joints; he had found it best to rest the joint, allow adhesions to form, and then break them down. If active exercises were prescribed for shoulder adhesions, the patient used the scapula to increase the range, and the stiff shoulder was not improved.

Mr. **Whitchurch Howell** echoed the welcome of other speakers to Sir Robert Jones.

Dr. W. P. **Kennedy** asked if Sir Robert had much difficulty in educating patients to move the muscles round a stiff joint.

Dr. E. F. **Cyriax** suggested that "locked vertebræ" were due to muscular spasm round a dislocation.

Sir **Robert Jones**, in reply, said he had never been able quite to see how vertebræ became displaced, and yet the striking experiences related by many people seemed to suggest that vertebræ might be shifted. Sacro-iliac displacement certainly occurred, and yet it had never been seen in a radiograph. He thought it was very common indeed to call other conditions of a joint "displaced cartilages," although he would not say that a displaced cartilage could not be cured. Many northern football teams refused to have manipulation, as the results had proved so unsatisfactory. Sometimes patients could only be taught movements by practice on the sound side.

SECTION OF THE HISTORY OF MEDICINE.

At a meeting of this section on April 6th the chair was taken by Dr. R. O. **Moon**, the President, and a paper on Medical, Theological, and Popular Views concerning the

Nightmare

was read by Dr. **Ernest Jones**. During the last 30 years, he said, knowledge had been acquired which put the pathology of nightmare on an entirely new basis, but this knowledge was unfortunately the possession of but a few, the majority still holding an attitude comparable with that of a collection of mediæval medical men towards, for instance, the pathology of malaria. In early days all illness had been believed to arise from malignity, either endogenic or exogenic; the development of scientific medicine had meant the de-moralising of pathology. In laughing at this view, however, the scientific workers had made the old mistake of emptying the baby with the bath, for in some departments of pathology the moral aspect undoubtedly played a part. Few problems illustrated this fact better than the pathology of the nightmare. The early view had been that the nightmare was an attack by a throttling demon. The first suggestion that gastric disturbances produced it was found in the works of Galen, followed by Paulus Ægineta.

The chief characteristics of the nightmare were an oppressive dread, an overpowering sense of suffocation, and helpless paralysis. The somatic theories of its pathology were of subjective origin, arising from the subconscious minds of those who believed them. There was a striking lack of correlation between the supposed causes and the appearance of actual nightmare. Nightmares were pre-eminently mental manifestations based on acute anxiety; anxiety to anything approaching this degree was definitely pathological. Freud had shown the intimate connexion between morbid fear and repressed sex. Only a certain class of subject was liable to nightmare; these people were suffering from an unconscious psycho-sexual conflict, which had usually been stirred by some incident just before the dream; they had a strongly masochistic psycho-sexual constitution, and their repression always dated from very early infancy and related to incest. The attacking animal usually represented a parent. The psychopathological theory did not dismiss the physical theories entirely; when a morbid fear was present it could be excited by an actual situation as well as from its sources in the unconscious mind.

THE RELATION WITH EROTIC DREAMS.

Nightmare and erotic dreams in general were only distinguishable in extreme forms. Few dreams culminating in emission were altogether free from anxiety, and there was every grade of intermediate dream experience. The greater the repression the greater the fear produced by a voluptuous impulse arising during sleep. The ecclesiastical discussions on nightmare in the Middle Ages closely resembled a modern judicial inquiry into rape; the subjects might willingly submit to the attack of the incubus or might be tormented entirely against their will. "Nightmare" and "Incubus" simply meant a lewd demon who visited by night. The popular view, dating from prehistoric times and accepted by the church, was that erotic dreams and nightmare arose from sexual desire in some supernatural being; while the medical view ascribed them to impulses within the body. The medical view had prevailed over the popular view for erotic dreams in the sixteenth century, for the nightmare only in the eighteenth century. The two views had much of interest in common. The modern psycho-analytical interpretation held that both nightmare and erotic dreams were endogenic and arose from repressed sexual wish, thus combining the truth of the two older theories. There had to be error in the theory in order that its believers might escape the sense of guilt; the sexual origin was projected either on to other beings or on to some inanimate process in the body.

The **Chairman** asked whether true nightmare was very common. He recognised the intermixture of pleasure and pain, but did not think fear was on the same footing. He suggested that Freud had confused genus and species—generalised libido and sexual desire; his doctrine was just as materialist as any other variety of scientific materialism.

Dr. **William Brown** said that throug ages philosophers had shown flashes of illu about the dream. The dreams of antiquity ill psychological principles. Plato had reg as a manifestation of the lower self. realised, as Aristotle had, that the dream experiences. Spinoza had said that it work pendently of the control of external im and therefore became ridiculous. Dreams guardian of sleep, taking up into themselves dis stimuli, but in extreme anxiety-dreams this r William said he had some difficulty in deciding hether he was dealing with tiny lymphatic vessels id glands, instead of nerve-fibres and ganglia, in e course of the operation. In an infant, he was not ıre that frank exposure of the lumbar sympathetic ıain on the left side and division of the trunk above ıe second and below the fourth ganglion was not the ore satisfactory operation, ramisection being perrmed at the same time. The constipation was ımpletely relieved by the operation, and this relief ıd now continued for 14 months.

After operation, a full-sized sigmoidoscope was passed ırough the pelvirectal sphincter on a few occasions, the ılon being emptied by means of an irrigating tube. Two months after operation a barium meal and enema demonstrated the pelvic loop of colon still dilated but greatly reduced in diameter. The transverse colon was also considerably reduced. Seven months after operation marked dilatation was still present, but there was slight further improvement. The umbilical girth at the time of operation was 24¾ inches. Five days later it was 21¾ inches, and the latter measurement was the same two months later. Seen recently, the child's general health was good; the constipation was relieved, but distension remained.

Mr. A. B. Clery showed a boy, aged 6½, who was badly burned across the chest and neck, and successfully treated by a skin graft.

Mr. A. A. McConnell read a paper on Some Lesions in the Region of the Pituitary Body.

REVIEWS AND NOTICES OF BOOKS

iseases of the Kidney.

By W. Girling Ball, F.R.C.S. Eng., Surgeon to St. Bartholomew's Hospital, London; and Geoffrey Evans, M.D. Camb., F.R.C.P. Lond., Physician to the Hospital with charge of Out-patients. London: J. and A. Churchill. 1932. Pp. 424. 36s.

A book devoted exclusively to diseases of the idney is clearly an ambitious undertaking. It is good hat two writers of the calibre of Mr. Girling Ball nd Dr. Geoffrey Evans should have collaborated o produce this volume. The value of a combined nedical and surgical text-book on the kidney is xemplified sufficiently in one chapter only, that on ymptomatology. The surgeon confronted for example vith a case of renal hæmaturia is too often inclined o neglect the medical possibilities of the diagnosis, ut he will not do so if he has digested the information iere supplied. Again in the account of the examinaion of a urinary case, the value of collaboration is vident.

The surgical part proper opens with an account of the ongenital lesions of the kidney and ureter: there are iumerous illustrations with short clinical descriptions ippended of which full use must be made to amplify the text. These illustrations are all good, and help he story, while certain of them are admirable. The characteristic mesially directed lower calyx in horse-shoe kidney is only mentioned beneath an illustration in another chapter (Fig. 52) and not in the general text, but no careful reader should be embarrassed thereby. In the discussion on movable kidney there is evidence of a proper appreciation of the value as well as the limitations of surgical treatment, and in the advice upon kidney injuries conservative methods are rightly recommended where possible, the indications for surgical intervention being adequately summarised. The chapter on hydronephrosis is of particular interest and includes mention of the majority of the accepted causes of the condition. The exact views of the authors on the question of hydronephrosis of uncertain ætiology are not made quite clear, for whilst on page 157 we find the term "congenital" hydronephrosis allotted to those cases occurring in fœtuses or young children, or due to some congenital abnormality in position or structure of the kidney or its vessels, there are subsequently frequent references to cases regarded as congenital hydronephroses to which these criteria do not apply. It is generally recognised by urologists that the so-called abnormal vessels frequently found in adult hydronephrosis are not primarily abnormal, and that their kinking effects on the uretero-pelvic junction are only produced after the hydronephrosis has already commenced to form. There is a vessel described as abnormal in the caption to an illustration on page 174 which would appear to be the normal inferior branch of the renal artery; if this is so, the case should rightly fall into the group classified as hydronephrosis of uncertain ætiology instead of being regarded as a congenital hydronephrosis. It is a small point, and the authors' interpretation of the picture may be right; the doubt is raised to show how carefully the book needs to be read. The discussion on the ætiology of the unexplained cases includes mention of the theories ascribing it primarily to inflammation, congenital narrowing, and spasm respectively of the uretero-pelvic junction. The question of pyelovenous back-flow is dealt with in the pathological section.

In the chapter on non-tuberculous infections the classification adopted is founded on a distinction between cortical and pelvic infections, with acute suppurative nephritis as a connecting link; this is a sound basis on which to describe these infections and has led to an orderly account. *B. coli* infections in general are regarded as being hæmatogenous in the majority of cases, whilst tuberculous infection is stated to be blood-borne when the primary source is distant, and lymphatic when the primary source is in the neighbourhood of the kidney. The less controversial subjects of tuberculosis and calculus are well described, and the chapter on renal tumours includes a simplified classification of the malignant renal growths; a few histological microphotographs might be included in this section with advantage. The account of operations on the kidney supplements those in the standard text-books of general operative surgery, but in none of these, we think, will be found such close descriptions of the difficulties and risks that may be encountered or greater descriptions of the routes of operation.

Certain portions of the book dealing with what are usually considered the purely medical aspects of renal disease would be disappointing if it were not remembered that to expect a lucid exposition of a subject where so much of our knowledge is imperfect would be illogical. On page 48 the term "uræmia" is properly limited to those toxæmic states which complicate or terminate severe kidney disease and in which urea retention occurs, but in the sentences immediately following this distinction disappears, while the conception that pseudo-uræmia is a consequence of hypertension as opposed to a chemical phenomenon is not sufficiently brought forward. These passages form an example of the demand for close reading which is made. The truth may easily be sacrificed in the attempt to be clear and simple, but nothing of the sort is found here;

She had had acute attacks of pain in the left side, and in the last she nearly fainted. Attempts at micturition produced cramp-like pains. On opening the abdomen a moderate amount of blood was found in the left half of the pelvis. The left tube, which was the size of a sausage and contained an ampullary mole, was removed. After the operation she bled for three days, but there was no suggestion of labour pains. The size of the uterus corresponded with the period of amenorrhœa, and natural delivery of an 8 lb. child occurred.

It was clear that many cases had been included in this title which should not have been. The maximum incidence of this condition was in the active child-bearing period—i.e., 25 to 35 years of age. It seemed that previous pregnancies predisposed to the condition, and hence that postnatal complications were causal factors. There were no definite criteria available on which to base a prognosis as to the fate of the intra-uterine ovum. Cases in which uterine pregnancy occurred in the presence of a retained ectopic pregnancy should be placed in a separate category. A retained fœtus was not apt to cause symptoms, and even a subsequent intra-uterine pregnancy, with disturbance of the abdominal contents, was but little likely to provoke them. Neither was the retained fœtus likely to cause difficulty in labour.

DISCUSSION.

Mr. CLIFFORD WHITE referred to a case of extra-uterine pregnancy in a woman who had had a child five years before, and a miscarriage six years before.

She was admitted as an emergency; she had had severe vomiting and bearing-down pains. On admission there were signs of acute intraperitoneal hæmorrhage, and an abdominal mass was evident. Laparotomy was immediately done, and the left tube was found to be gravid, the uterus being enlarged to the size of a 12-weeks' pregnancy. Both ovaries were healthy, and neither was removed. In a few months she was delivered of a living child of 8 lb. 13½ oz. weight, and it weighed 9 lb. 3 oz. when the mother was discharged.

Mr. W. C. W. NIXON spoke of the significance of a purple discoloration around the umbilicus in cases of ectopic pregnancy.—Mr. A. J. WRIGLEY said that at St. Thomas's Hospital a large proportion of cases of ectopic pregnancy were operated upon by the general surgeon. Salpingitis was present in one case in five.—The PRESIDENT said it had recently been his view that there must be some defect in the tube in these cases, perhaps a low degree of inflammation. Non-inflammatory kinks were probably a common cause of tubal gestation.—Dame LOUISE MCILROY asked whether Prof. Murray had had experience of pain being referred by the patient to the shoulder in these cases; she had had one or two in which that was so. She also asked whether he always removed the affected tube. In one or two cases in her experience the ovum was projecting from the tube, and after she squeezed it out complete recovery followed.

Prof. MURRAY replied that he was not aware of having seen a case with purple discoloration. In only a few cases was pain referred to the shoulder-tip. In few of his cases was there a large effusion of blood; he had never intentionally conserved a tube unless there was a special reason for doing so.

Mr. DOUGLAS MACLEOD read a paper on two cases of

Struma Ovarii.

An alternative term, he said, was ovarian goitre, and the condition was an ovarian tumour, most of which consisted of thyroid tissue. These cases supplied information favouring the teratomatous origin of these tumours. Thyroid tissue was a small part of teratomatous cyst, and in some cases it grew out of all proportion to other structures. He thought that sytematic examination would show that thyroid tissue was present in tumours of this region more commonly than was generally believed; it was usually of the colloid type. In the subjects of these tumours menstrual irregularities were frequently noted, and usually the women were multiparæ. Yet symptoms of hyperthyroidism were conspicuous by their absence. The first of these tumours contained hair, skin, and sebaceous material, and the macroscopical appearance was a honeycombed one. The second case was complicated by an inflammatory condition. The thyroid tissue was in the lining of the cyst, and so was actually part of it.

The PRESIDENT described two cases of

Implantation-endometriomata.

He said he had had, in all, six cases of endometrioma in the abdominal wall; they had followed either abdominal curettage or myomectomy. A lump appeared in the abdominal scar, and gradually increased in size, in a period of from two to six years. In one of these present cases the lump was the size of a walnut, and it became very tender and painful at each monthly period. On excision he found the tumour to consist of a strong fibrous matrix, with hæmorrhagic areas and typical endometrial tissue, uterine glands, and stroma. He brought the matter forward to impress the lesson that in abdominal curettage and myomectomy it was very important to cover the wound edges with linen—better with rubber—sheeting; otherwise scrapings might get implanted and cause such a swelling as that described.

Prof. MURRAY said he had done myomectomy and intra-abdominal curettage many times, but had not yet had a case of implantation tumour, though he had never troubled to protect the edges of the abdominal wound.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

AT a meeting of this section on April 1st, with Mr. R. ATKINSON STONEY, the President, in the chair, a *case of*

Hirschsprung's Disease

was reported by Sir WILLIAM WHEELER.

The patient was a boy, aged 2 years, suffering from increasing constipation and marked abdominal distension. Aperients and enemata had failed to act, and distension was progressive. There was the usual absence of signs of obstruction and toxic symptoms were not marked.

The case presented one unusual feature. The pelvic colon was not dilated for two or three inches above the pelvirectal sphincter, and the rectum was normal. Radiography before operation showed an enormous *loop* of descending colon. The barium meal was visible a week after ingestion, notwithstanding repeated washing out of the colon. The barium enema also revealed the colon to be five or six times the normal diameter. The ascending colon was not dilated, and the transverse only moderately so.

The operation, performed in February, 1931, was that recommended by Rankin and Learmonth. The posterior peritoneum was divided from the promontory of the sacrum to the origin of the inferior mesenteric artery. The presacral nerve and its branches were not *found* easy to define, but communicating filaments from the second, third, and fourth sympathetic ganglia were divided and the area cleared of loose connective tissue. The inferior mesenteric artery near its origin was similarly denuded, *but* no very definite ganglia were found. The operation was rendered more difficult by the attachment of the mesocolon *to* the right of the middle line.

CREMOR ALKALINUS 'A.&H.'

For the Intensive Alkaline Treatment of Gastric and Duodenal Ulcers

For the convenience of practitioners the approved formulæ are prepared in the form of simple creams which are exceptionally free from grittiness.

In 8 oz bottles for prescribing.

In 80 oz bottles for dispensing.

Descriptive booklet and clinical trial sample sent post free on application.

Formula A

Sod. Bicarb.	2 parts
Mag. Carb.	4 parts
Calcium Carb.	4 parts
Bismuth Carb.	1 part

This is the standard preparation.

Formula B

Sod. Bicarb	2 parts
Mag. Carb.	3 parts
Calcium Carb.	4 parts
Bismuth Carb.	2 parts

This is employed in cases where Formula A proves too laxative.

Formula C

Sod. Bicarb	3 parts
Mag. Carb.	8 parts
Calcium Carb.	12 parts

Specially suitable for cases in which a bismuth-free preparation is desired.

Formula D

Mag. Carb.	4 parts
Calcium Carb.	6 parts
Bismuth Carb.	1 part

For cases where the use of Sodium Bicarbonate is regarded as disadvantageous.

Formula K

Sod. Bicarb.	2 parts
Mag. Carb.	3 parts
Calcium Carb.	4 parts
'Osmo' Kaolin	2 parts

The bismuth is replaced by colloidal kaolin which possesses marked toxin-adsorbing properties.

Cremor Alkalinus "A. & H." Lozenges

Prepared from Formula C. Convenient for carrying in the pocket.
Each lozenge contains 15 grains.

ALLEN & HANBURYS LTD.

LONDON, E.2

Telegrams; "Greenburys Beth London"
Telephone: Bishopsgate 3201 (10 lines)
[*See also pp.* 22, & 23.]

The authors state that the classification and nomenclature of Bright's disease follow the British medical tradition, and that there is no radical departure from traditional teaching, despite American, German, or French views on nephritis. It was a wise decision, however, to accept the conception of nephrosis as standing between toxæmic kidney on the one hand and acute nephritis on the other, and the design to follow British medical tradition has not prevented the authors from recognising the modern conceptions of focal embolic nephritis and hyperpiesia. The establishment of "toxæmic kidney" as an entity is not easy. On page 201, for example, it is stated that this group includes all those forms of kidney disease, histologically chiefly degenerative, which are conterminous with their cause, a view which does not harmonise with the inclusion in this group of many of the most disastrous types of nephritis occurring in pregnancy. The student of modern work on renal disease in its medical aspects is accustomed to select the group described as "chronic interstitial nephritis" as a touchstone to the author's general conception. When this is applied to the present work some disappointment will be felt at the nebulous character of the group described. The second paragraph on page 258 appears to define the cases included under this term, but after close study we find ourselves unable to form any clear idea of what the authors really wish to be included under this heading.

The book contains useful descriptions of technical methods, is beautifully illustrated—there are eight coloured plates and 159 text-figures—and forms a valuable addition to existing literature on the subject.

Alcoholic Fermentation.

Fourth edition. By ARTHUR HARDEN, Ph.D., D.Sc., LL.D., F.R.S., Emeritus Professor of Biochemistry, University of London. London: Longmans, Green and Co., Ltd. 1932. Pp. 243. 15s.

THIS standard work, which has now reached its fourth edition, needs no introduction to biochemical readers. Alcoholic fermentation is now a subject of its own, and the advances in recent years have been so great that, as Prof. Harden says, it has been all but impossible for him to cover the additions to the literature made since the publication of his last edition. He succeeded in summarising the most important papers, and has included all the recent advances. The summary of the more recent observations of Euler and Neuberg is a brilliant piece of work. This work is indispensable to anyone interested in enzymes in general and in alcoholic ferments in particular.

Recent Advances in Botany.

By E. C. BARTON-WRIGHT, M.Sc. Lond., Chief Assistant for Research in Virus Diseases of the Potato at the Scottish Society for Research in Plant Breeding, Corstorphine. London: J. and A. Churchill. 1932. Pp. 287. 12*s.* 6*d.*

THE subject matter is divided into nine chapters, of which one is devoted to some theories regarding plant structure and one to palæobotany and experimental methods in relation to the species problem; the fungi take up three chapters, and the brown and red algæ two. The last chapter dealing with the virus diseases of plants is likely to be of most interest to our readers, for it provides in easily accessible form a summary of the information so far obtained with regard to this obscure subject in plants. In the selection of material for review the author has omitted special reference to the genetical and cytological aspects of the subject as both these branches are to be treated by other authors in future volumes. Where necessary, references to literature of pre-war date have been included in order to present a connected picture of each subject dealt with. The book should prove particularly useful to students reading for final examinations in botany.

Clinical Lectures on Psychological Medicine.

By HENRY YELLOWLEES, O.B.E., M.D., Physician for Psychological Medicine, St. Thomas's Hospital. London: J. and A. Churchill. 1932. Pp. 310. 12*s.* 6*d.*

THE range of these clinical lectures is very wide: the whole of mental disorder is discussed in 14 entertaining sections of a book which has retained the familiar language, the discursiveness, pointed *illustrations, and lively anecdotes* which stimulate the student's interest. The psychoses are dealt with mainly from the Kraepelinian standpoint, with brief reference to the writings of Meyer and McCurdy; the psychoneuroses according to the modified Freudian view now current among most non-Freudian psychotherapists in England. On some points the author's statements are disputable—e.g., his insistence on insight as an unfailing touchstone permitting sharp distinction between psychoses and psychoneuroses, but as the work is not intended for psychiatrists, such part-truths may be permissible. The book is professedly elementary; it would therefore be unreasonable to complain that it is dogmatic. The style is easy, and in places almost rollicking; the author is a psychiatrist of much clinical experience and common sense; and the simple, confident mode of presentation is well suited to the purpose of instructing medical students and general practitioners in the outlines of psychiatry. The final chapter, an address to psychologists, contains a vivacious criticism of the Freudian position, ending with a serious estimate of the ultimate task of psychology which Dr. Yellowlees sees as bridging the gulf between science and the mysteries with which religion alone deals.

A Synopsis of Pharmacology.

Second edition. By the late DOUGLAS COW, M.D. Revised by G. NORMAN MYERS, M.D., B.S., M.Sc., B.Sc. Hons., A.I.C., Beit Memorial Fellow, Pharmacological Laboratory, University of Cambridge. London: J. and A. Churchill. 1931. Pp. 171. 7*s.* 6*d.*

THIS small book, originally dedicated by its author, the late Dr. Cow, "to that Great Army of Medical Students, some 80 per cent. of the whole who in examinations are within measurable distance of the Rubicon that divides the approved from the rejected," quickly proved its worth. It is described as a synopsis, but it is rather more than that, for it contains an accurate and fairly complete account of the essentials of modern pharmacology. It could not be used as a text-book by any one ignorant of the facts, but it will serve to refresh the memory of the student who has read or heard something of the subject. The drugs are arranged in alphabetical order, repetition is avoided by a system of cross-reference, and there is a pithy discussion of the main facts of each. Dr. Myers has carefully revised the first edition to bring it up to date, and his policy of keeping prominently in view the practical needs of the student, should ensure for the second edition the usefulness and popularity of the first.

CREMOR ALKALINUS 'A.&H.'

For the Intensive Alkaline Treatment of Gastric and Duodenal Ulcers

Formula A

Sod. Bicarb.	2 parts
Mag. Carb.	4 parts
Calcium Carb	4 parts
Bismuth Carb.	1 part

This is the standard preparation.

Formula B

Sod. Bicarb.	2 parts
Mag. Carb.	3 parts
Calcium Carb.	4 parts
Bismuth Carb.	2 parts

This is employed in cases where Formula A proves too laxative.

Formula C

Sod Bicarb	3 parts
Mag Carb.	8 parts
Calcium Carb.	12 parts

Specially suitable for cases in which a bismuth-free preparation is desired.

For the convenience of practitioners the approved formulæ are prepared in the form of simple creams which are exceptionally free from grittiness.

In 8 oz bottles for prescribing.

In 80 oz bottles for dispensing.

Descriptive booklet and clinical trial sample sent post free on application.

Formula D

Mag. Carb.	4 parts
Calcium Carb.	6 parts
Bismuth Carb.	1 part

For cases where the use of Sodium Bicarbonate is regarded as disadvantageous.

Formula K

Sod. Bicarb.	2 parts
Mag. Carb.	3 parts
Calcium Carb.	4 parts
'Osmo' Kaolin	2 parts

The bismuth is replaced by colloidal kaolin which possesses marked toxin-adsorbing properties.

Cremor Alkalinus "A. & H." Lozenges

Prepared from Formula C. Convenient for carrying in the pocket.
Each lozenge contains 15 grains.

ALLEN & HANBURYS LTD.

Reminders and Suggestions

For the
Treatment of
INFLUENZA, PNEUMONIA,
COUGHS, COLDS, BRONCHITIS, etc.

KINECTINE	An organic arsenical salt of Quinine indicated in Influenza, Acute Coryza, etc.
Tubes of 10 Tablets:	*Dose—One three times a day.*

CRYOGENINE (Lumière)	A particularly safe and reliable analgesic and antipyretic in all febrile conditions. Bronchitis, Pneumonia, Influenza, Pleurisy

Powder and Tablets: Dose—From 0·50 to 2·50 gm. daily as required.

ORARGOL	An electrically prepared Gold-Silver Colloid for general antisepsis and effective colloidotherapy.

Ampoules of 5 c.c. and 10 c.c.

By intravenous or intramuscular injection Orargol is capable of aborting serious cases of Influenza and Pneumonia, and exerts an antitoxin-like effect in acute infectious conditions.

Also supplied in special O.R.L. Outfit for Nasal Irrigation in the treatment of Rhinitis, Tonsillitis and Naso-pharyngeal inflammations.

Extremely valuable as a prophylactic against Colds and Influenza.

SYRUP CREOSAL (Dubois)	A combination of Guaiacol, Calcium and Phosphoric Acid pleasantly flavoured with Syrup of Orange Flower & Cherry Laurel.

An excellent specific for Coughs—whatever their origin—Bronchitis, Laryngitis, and all Catarrhal Conditions.

SYRUP PERTUSSIS (Gabail)	A combination of deodorised Valerianate, expectorants and sedatives presented in a palatable form with Syr. of Raspberry.

An effective medicament for the Paroxysms of Whooping Cough.

TRAINING IN TUBERCULOSIS.

THE Joint Tuberculosis Council consists of 30 members representing the various societies interested in tuberculosis, with delegates from the Society of Medical Officers of Health, the British Medical Association, the Ministries of Health and Pensions, and eight coöpted members. The Council was formed in 1924 for the purpose of coördinating the study and treatment of tuberculosis and to promote research. Questions are referred to it by government departments, local authorities, and workers in various fields. Important memoranda on notification, disinfection, and employment have been issued, and in 1930 a scholarship tour was arranged in collaboration with the Sun Life Assurance Company of Canada. A report just issued by a committee of the Council discusses the problem of teaching tuberculosis to students and officers of the tuberculosis service. Most of the tuberculous patients who used to attend teaching hospitals now attend the tuberculosis dispensaries or from there are sent to one of the special institutions provided by local authorities. It is possible at the moment for a medical student to present himself for his final examination without having seen a single case of pulmonary tuberculosis, although each year some 40,000 people die of this disease in England and Wales alone. Apart from its importance as a disease, tuberculosis has some claims to be considered a subject on which medical teaching should be based. The teaching of tuberculosis to students would give them an insight into the relationship between social and industrial conditions and the incidence of disease. It would also assist them to know how to examine the chest, for physical signs and X ray interpretations can be learnt better at a chest hospital than elsewhere. Again, the principles of orthopædics can be well taught at a hospital for surgical tuberculosis. To arrange for a more thorough teaching of tuberculosis need not increase the burden of the student whose curriculum is already overcrowded. A knowledge of tuberculosis would help him to understand the principles of pathology and treatment as applied to other diseases; there is no subject better suited for instructing students in first principles. While the claims of syphilis, mental disease, or rheumatism may be admitted, tuberculosis stands alone in this: although one of the most common causes of illness and death it is becoming more and more uncommon in the out-patient departments and wards of teaching hospitals, except such as have a tuberculosis dispensary.

The report makes the following recommendations for training:—

1. That with some notable exceptions the present methods of training students in tuberculosis are inadequate for lack of arrangements ensuring close coöperation between the public health service, and the medical schools and teaching hospitals, thus not utilising clinical material in the dispensaries and sanatoria *belonging to public authorities.* The General Medical Council might urge upon these schools and hospitals the importance of coöperation.
2. That the arrangements for teaching at certain medical schools, where medical officers of the tuberculosis service are lecturers in tuberculosis and have charge of beds, are worthy of consideration at other medical schools where no arrangements at present exist to utilise the personnel and material available under the tuberculosis schemes of the local authorities.
3. That, where Local Government grants are given to assist medical schools or teaching hospitals, it would be reasonable for the authorities to require, as a condition of the grant, proper coöperation with the work of tuberculosis schemes.

These recommendations are worthy of careful consideration, and although it may be impossible or unwise to give to all students a special training in tuberculosis it is undoubtedly a disease with which they should be familiar before qualification. The work of the tuberculosis officer is becoming more and more specialised, and only a man of high professional standing with experience in all forms of tuberculosis can act adequately as consultant and adviser to the general practitioner. It is reasonable to require that every tuberculosis officer should have hospital beds at his disposal and that, where convenient, the medical staff of a sanatorium should be responsible for some clinical work outside the institution. The report is signed by twelve members of the Council and the convener, Dr. G. LISSANT COX. Copies may be obtained from Dr. ERNEST WARD, hon. secretary of the Council, 123, Torquay-road, Paignton, Devon.

◆

STREPTOCOCCAL INFECTION.

THE subject of this year's Milroy lectures has been aptly chosen. Since the war the volume of original work on streptococcal infection has been immense though of very various value. With some of that work Prof. C. C. OKELL has been intimately associated, and his own contributions have been among the most enlightening. These years have seen a return to many ideas which were long forgotten: in the latter part of the nineteenth century, for instance, both the toxic properties of streptococci and the streptococcal ætiology of scarlet fever were well accredited theories. There are now many established facts to go upon and the time was ripe for the comprehensive summary and criticism which the lecturer concludes in our present issue.

To many surgeons and physicians the present position is a disappointing one. It is very true that scarlet fever is now a relatively slight disease, that the terribly virulent cases of cellulitis and septicæmia are rarer. As Prof. OKELL admits, this result is a by-product of medical hygiene, if in fact medicine can claim any credit for it. In much the same way small-pox appears to have lost its virulence in an increasingly unvaccinated community. This diminished virulence of the streptococcus has lasted for 50 years; and that is a good omen for its perpetuity. But puerperal sepsis remains, almost unaltered in virulence or case-incidence, and the history of epidemic disease should make us chary of hasty optimism. Moreover, experience is teaching that serum therapy has narrow limitations. Acute streptococcal infection is very often the result of an inconsiderable accident; it is an acutely painful disease, and its too often fatal outcome renders it the most distressing of conditions to treat. The impotence of the physician, dealing with a patient, often young, faced with the fatal outcome of a trivial wound, and relatives appalled by a sudden dangerous illness supervening on a state of perfect health often force him to premature incisions which are worse than useless, and make him anxious to use every suggested remedy. Antitoxic sera have been very fully exploited; they have their uses, and will probably always be used; but they are far indeed from proving of universal value. Under these conditions Prof. **Okell**'s lectures may be considered as an expert's report in the breathing space that follows an unsuccessful attack in war. Here is all that experience has taught, and here success and failure are weighed. We have learned a great deal about the enemy; we are glad to know that, with or without our assistance, he is losing ground. We have evolved a few weapons, but they are not enough. Where are we to look in the future? Perhaps, for the present, to the clinician rather than the bacteriologist. In a streptococcal infection which is to have a fortunate outcome, certain features are constant. A continuous fever becomes intermittent; what is the cause of these remissions, and how can we prolong them, and thus relieve the heart? A spreading cellulitis becomes localised; a septicæmia changes to pus formation. How are we to encourage these obviously beneficial changes? Laboratory work has, for the moment, reached the end of its tether; the natural course of disease must be studied, and its lessons must be applied.

If the streptococcus, the pneumococcus, and the staphylococcus were removed from the list of human parasites, infection even to-day in civilised countries would be negligible as a cause of death. They are universal in the bodies of men and animals as saprophytes; we cannot hope to eliminate them by hygienic measures. There are no antidotes for their infections truly and comprehensively specific. Chemotherapy, to date, has helped very little; and **Ehrlich**'s aspiration towards a great universal bactericidal drug seems as far off as ever. Such a situation cannot but stimulate research workers to a fresh outlook and new lines of attack. "When I fixed unwearied eyes on them," said **Leeuwenhoek**, reporting the discovery of bacteria, "I saw their bodies bending with languid motion, making little progress." It is something to be convinced, once again, from Prof. **Okell**'s lectures, that the eyes of the bacteriologist are still unwearied.

CLINICAL RADIOLOGY.

During May, June, and July a course of twelve clinical lectures is to be given at the Radium Institute in London, which is now a constituent part of the National Centre and Post-graduate School of Radiotherapy. The lectures, which are open free of charge to registered medical practitioners, will be accompanied by demonstration of cases illustrating treatment by radium of many regions of the body including skin, tongue, larynx, nasal sinuses, pharynx and œsophagus, breast, rectum, bladder and prostate, the use of radiotherapy in gynæcology, the treatment of sarcoma, and the application of deep X ray therapy. The lecturers are either on the staff of the Centre or members of the teaching staff of various London hospitals, and the course follows in many particulars the precedent of the pioneer course in radium treatment given at the Westminster Hospital in 1929, and embodied in a volume of the hospital's reports.[1] That course was offered in the spirit of Trousseau who, in opening the first session of a new academic year, was accustomed to tell his hearers that he expected to lear as much from them as they from him; and th cognate aim of the Post-graduate School is t stimulate interest in therapeutic radiology i London, especially among young consultants an the resident staffs of the teaching hospital For this reason the lectures have been spread ove three months at weekly intervals instead of bein concentrated as before in a course of a month duration. The Radium Commission has bee conscious from the first that the progress of radi therapy is closely bound up with the popularis tion of the principles of its application throug such channels. Those who know most reali best how imperfect is our knowledge of the actio of radium upon the tissues. As Prof. **Sidney Ru** points out in his paper in our present issue we a still more ignorant of the general physiologic effects of gamma rays than we are of their immedia effects upon cell life, whether malignant or othe wise; it is, he thinks, an encouraging sign th physiologists are beginning to include radiation an instrument for their own use, for this will bene not only physiological study but will in tu yield results having an important bearing radiotherapy. A course of lectures such as th now planned, if it should succeed in attracting number of those who are in touch with the mode technique of treating disease and have not forgotten the physiological principles of th earlier study, should produce just the impul to progress which radiotherapy needs. Prof. Ru indicates directions in which study might be fruit. It is well known that large doses of gamm rays have a destructive action upon the bon marrow; it is not so generally known that cells which disappear from the circulation not necessarily destroyed, they may be no mo than temporarily withdrawn. The importan of the part played by the normal cells of the bo the vicinity of the malignant growth is still sufficiently recognised; he would like all who e in touch with the clinical effect of radiation bear in mind to what an extent some of the vital unctions of living tissues are put out of action y a quantity of radiation which has but a trifling tion upon their other processes. A case recorded y Miss WINIFRED BUCKLEY on p. 884 of our present issue raises, without answering, several of these questions.

[1] Westminster Hospital Reports, vol. xxi. Radium Pract 1929. Edited by E. Rock Carling. London: H. K. Lewis. 19

The course of lectures, which we commend to the attention of all our readers, will be given on Wednesday afternoons at 4.30 P.M., beginning May 4th, at the Radium Institute, Riding House-street, London, W.1. Particulars may be had from the Secretary of the Institute.

ANNOTATIONS

THE INDIAN MEDICAL COUNCIL BILL

THE proposal to set up an All-India medical ouncil has been approved by the Secretary of State, nd a Bill has now been introduced into the Indian egislative-assembly. Several attempts have been nade to bring the various interests into agreement, but so far without definite result. The chief obstacle no doubt has been the feeling of resentment at the action of the General Medical Council in withdrawing recognition of Indian degrees. Now that the political horizon is clearer, and there has been time to appreciate the motives of the G.M.C., agreement has been brought nearer. But there are still difficulties to be surmounted, and the Bill, if it becomes law, will have to be a compromise. The draft is entitled "A Bill to establish a Medical Council in India and to provide for the maintenance of a British Indian Medical Register." It is proposed that the council shall consist of a president, to be nominated by the Governor-General in Council, or alternatively elected from amongst themselves; one nominated member from each governor's province and three from the government of India; and one elected member from each British Indian university and each provincial committee of the council. The total number of members to begin with would be 28, and the council would meet at least once in each year, much of the routine work being done through provincial committees. Such committees are to be constituted in all provinces in which a provincial medical council exists, and will include all members possessing recognised medical qualifications. The functions of the council will include regulation of medical standards and inspection of examinations, the maintenance of a register, and recognition and withdrawal of recognition of medical qualifications. Decision as to erasure of names from the register for improper conduct will be taken by provincial medical councils, or provincial committees of the central council, or the central council itself, under varying circumstances. It is recognised that the powers which the provincial councils have hitherto exercised will be affected, but this is inevitable, and the provinces will have to be asked to submit in certain matters to the jurisdiction of the All-India Council. Much work will still remain for them to do. No mention is made in the draft of the licentiate class. There was a general consensus of opinion at the conference of June, 1930, that the central council should at first, at any rate, deal only with graduate qualifications; but nothing in the Bill excludes non-graduates permanently. Organisations of licentiates have petitioned the Government of India for inclusion and there are many arguments in its favour. Licentiates far outnumber graduates. They fill a very important place in the medical arrangements of the country, and their education and status are in need of regulation and standardisation. It is significant that the licentiates themselves are continually pressing for extension of their curriculum, and improvement of the medical schools in which they receive their training. Criticism has also been aroused by the fact that there is no provision in the Bill for the reservation of official appointments and other professional privileges to registered practitioners. It is satisfactory to note that the main principle of the Bill has met with general approval by the profession at large.

THE CAUSES OF HOOKWORM ANÆMIA.

RATHER over a year ago[1] under this heading we summarised evidence for the conclusion that waste of blood by hookworms was the essential cause of the anæmia they produce. Since then the matter has been carried for one species from the region of reasoned conclusion towards that of observed fact. By devising a clamp which, while not interfering with blood-supply, forms a small tank filled with normal saline, H. S. Wells[2] has watched the life of hookworms in the opened intestines of dogs narcotised with soluble barbital. The whole process can be seen when *Ancylostoma caninum* attaches itself near the tip of a villus, though the worm is in fact restless until it, so to speak, shoulders its way to a deeper and presumably more vascular hold. The blood-vessels of the selected villus dilate remarkably, yet hitherto it does not seem to have been suggested that a vasodilator is one of the substances secreted by the glands which open in or near the hookworm's mouth. Yet that would now seem to be the case, and the presence of such a body very obviously subserves the needs of a parasite which, as is now established, feeds ravenously on blood. Thus the hookworm's œsophagus acts as a sucker with a contractile rhythm which may run to 120 or even 250 pulsations a minute. When, by its active movements, the worm has pushed its mouth against the surface of a villus, this pumping mechanism is observed to fill the oral cavity and the œsophagus, first with intestinal epithelium and lymph, and then with blood. This blood the œsophagus passes on into the intestine, which in turn expels it in droplets per anum. By manœuvring the tails of hanging attached worms into the mouths of saline-filled pipettes, by counting a known fraction of the red corpuscles which were expelled into this fluid in a given time, and by comparing these with the numbers in the blood of the dog, Wells found that each female *A. caninum* wasted in this way an average of 0·84 c.cm. of blood daily. Now it is widely and emphatically maintained at the present time that a load of less than 25 hookworms is immaterial to man; yet on Wells's figures such a "light" load may imply a loss of half an ounce of blood daily, if these figures for this dog's hookworm can be applied to those of man. This he hesitates to do, in view of the general report that the stools of persons harbouring hookworms are not highly coloured, though he notes that there appears to be no means by which the amount of fæcal blood can be estimated, and that the conclusion that their colour shows that they do not contain blood is assumption. Some light was however thrown on this point by G. Duncan Whyte,[3] who reported 16 years ago from Swatow, China, that when there was rigorous abstention from meat for 72 hours (and meat must include cockles in this locality), evidence of blood could be obtained in fæces when fewer than 20 worms were afterwards recovered. The test used was an alkaline solution of phenolphthalein with hydrogen peroxide, and it was claimed that it would detect one part of blood in 800,000. Seeing that Looss reared *A. duodenale* to full growth in pups, it should be possible to resolve the doubts expressed by Wells as to whether these figures can be applied to the hookworms of man. Seeing the close resemblance in size and structure between *A. caninum* and *A. duodenale* it will be surprising if they cannot; but in the meantime few medical men will be disposed to question the wisdom of refusing to accept as immaterial to the host these "light" hookworm infections, particularly as the validity of the tests which have been held to exonerate them is not universally accepted.

---

[1] THE LANCET, 1930, ii., 1193.
[2] Jour. Parasitol., 1931, xvii., 167.

Moreover in instances where the passage of blood through the gut of hookworms has been slow, by the time it reaches the anal end the hæmoglobin has been reduced, so that whatever constituent of blood is of most value to it as food the host's hæmoglobin serves to supply the hookworm with oxygen. Further, a hookworm deprived of blood by detaching it from the mucosa becomes very sluggish, and in the one instance investigated ceased to oviposit. Yet if when replaced it is still vigorous enough to start feeding it rapidly regains its normal activities. It is not unlikely, then, that unsatisfactory nutrition of the worms, due to that poor quality of the host's blood which is the usual accompaniment of a heavy infection, may be a factor in bringing about that lessening of individual fertility which, as Clayton Lane showed,[4] accompanied increase in the hookworm load in those cases where reports were full enough for this matter to be tested. These ingenious experiments have attacked the hookworm problem from a new and promising angle.

ELECTROCARDIOGRAPHIC DIAGNOSIS OF MYOCARDIAL INFARCTION.

THERE are certain changes in the electrocardiogram that are almost pathognomonic of myocardial infarction—namely, well-marked deviation and rounding of the R–T segment, associated with low voltage ventricular complexes, and as a later development the disappearance of the R–T changes and appearance of a V-shaped T wave, either upright or inverted, and often of considerable amplitude. But the time of appearance and disappearance of these changes is variable, and it is possible for a normal curve to be obtained from a patient with myocardial infarction at two stages of the process: first in the earliest stage, and secondly some time after its occurrence. C. W. Holland and S. A. Levine [5] have studied the time relations of the electrocardiographic changes in 328 cases of coronary occlusion. Only 35 of these gave tracings at any time which could be regarded as normal in all respects. Eight were normal in the first few days after the attack, and the authors record the persistence of a normal curve up to a maximum period of ten days. A second group of 19 cases consisted of those from which characteristic curves followed by normal ones were obtained; a return to normal in one of them within four days illustrates how fleeting the changes may be. Finally there were nine who gave no abnormal curves whatever, although multiple tracings were not always taken. From these and other observations we may conclude that the electrocardiogram is undoubtedly of first importance in the diagnosis of myocardial infarction, but like every other means of investigation cannot be relied on exclusively. If a tracing taken from a patient in the early stages of an attack which presents the clinical features of myocardial infarction proves to be normal this is not nearly as strong evidence against the diagnosis as two or more normal curves taken at intervals of two or three days. On the other hand the finding of a normal curve a month or *more after an attack cannot* be taken as evidence that this was not due to coronary occlusion.

TUBERCULOUS MENINGITIS CURED BY DEEP X RAY THERAPY.

FROM time to time cases of tuberculous meningitis with recovery have been reported, but the total number is small and no satisfactory conclusions about the treatment of this terrible affection have hitherto been possible. Prof. Z. von Bókay,[1] of Debreczen in Hungary, now modestly reports success in five proved cases treated with deep X rays between May and August, 1931. It must be the first time that any one person has seen this number of recoveries and the results demand close scrutiny. The ages of the five patients were 12, 6, 4½, 3, and 3 years and the diagnoses were confirmed either by the finding of tubercle bacilli in the cerebro-spinal fluid or by the positive result of inoculating of the fluid into a guinea-pig. In one case, where bacilli had not been found in the fluid, recovery was so rapid after radiotherapy that the diagnosis of meningism was made, but five weeks later the post-mortem examination of an inoculated guinea-pig showed that the cerebro-spinal fluid had been tuberculous. The irradiation employed is described as follows: 162 kilovolts, 4 milliamperes with 0·25 of zinc and up to 3 mm. of aluminium filter, 150–200 R. units with a focal distance of 34 cm. This was applied to the base of the neck, forehead, and temporal regions, the exact situation irradiated varying slightly. Three to four applications were made in each case, with one to two days between the first two, and three to four days between subsequent applications. Recovery, where it took place, seems always to have been complete, a noteworthy feature being the rapid gain in weight as the meningitic symptoms disappeared. Loss of hair appeared to be the only deleterious result of the irradiation and it is possible that the alopecia produced may be permanent, although in one case hair was beginning to grow again over the bald areas a few days after the child left hospital. A more serious possibility is the subsequent development of hydrocephalus or mental deficiency, and it is too soon to say whether Bókay's patients will escape these sequelæ. Moreover, during the months in which these five cases were treated successfully there were elve similar cases in the hospital in which X rays iled completely. Discussing the question of what ctors make for success Bókay emphasises the fact at from a pathological point of view. tuberculosis ay be present either as a diffuse exudative process fecting all the meninges or as a local collection of berculous material in some portion of the meninges. he latter condition is closely allied to the "leaking iberculoma" seen in older children and adults who ive survived the presence of tubercle bacilli in the rebro-spinal fluid; and many of the reported cures" of tuberculous meningitis have been thought come into this class. It is impossible to decide ie exact pathological lesion in Bókay's cases. but ie clinical details given in his paper leave little oubt that they were genuine examples of tuberculous meningitis. This, of course, is often part f a generalised miliary process throughout the body nd, where this is so, cure within the skull cannot be xpected to save the child. Nevertheless, whatever he pathological condition, the cause of death is an ncreasing intracranial pressure and Bókay's point s that if this can be arrested a step forward has een made. The dosage of X rays employed is ery big, but in such a condition as tuberculous meningitis he holds that the *non nocere* principle can be justifiably abandoned and that intensive rradiation of the brain should be carried out without delay. There are many hundreds of fatal cases of tuberculous meningitis in this country every year. and there should be no difficulty in putting the new treatment to an early test.

NON-OPERATIVE TREATMENT OF SQUINT.

FOUR years ago[1] a new department was installed at the Royal Westminster Ophthalmic Hospital to deal with cases of incipient squint, and Mr. Montague L. Hine, in a recent paper,[2] gives a useful summary of the routine treatment as practised there. This treatment is directed to the ordinary cases of concomitant internal squint, not to the paralytic cases which are comparatively uncommon. The criterion for concomitancy is that the angle of deviation remains the same in whatever direction the eyes are looking. Its presence commonly depends on a defective fusion-sense or, as Mr. Hine expresses it, a defect in the degree of development of the inherent desire to use the eyes together, which is a normal instinct in mankind. Acting along with this there is often some upset of the normal relationship between accommodation and convergence or a measurable inequality between the refraction of the two eyes. These are the factors which can be remedied by spectacles. There may also be some lack of balance in the pull of the external muscles of the eyeball, not amounting to paralysis. Appropriate treatment depends on the age of the child. Under 18 months of age a squint, if only occasional. may be neglected; if constant, the fundus should be examined to exclude obvious causes of defective sight such as congenital coloboma or old scars of birth hæmorrhages. If it is concluded that the squinting eye ought to possess useful vision, an effort should be made to occlude the good eye for a time so as to avoid the amblyopia resulting from suppression of the image in the squinting eye. Over the age of 18 months it will be found possible in most cases for children to wear glasses when found desirable after retinoscopy under atropine. At this age small errors of astigmatism may be disregarded. When a squint is persistent and does not alternate, any further loss of vision may be prevented by continuing to occlude the fixing eye. In some cases atropine in the good eye may be sufficient to cause the originally squinting eye to fix.

For school-children who are being treated in the ordinary way by glasses and occlusion or atropinisation of the fixing eye, should this treatment prove insufficient the questions arise: for how long should the occlusion be continued? In cases where the squinting eye is nearly blind, if there is no improvement after a month either the occlusion has been inefficient or else the attempt to improve the vision of the squinting eye is hopeless; in other cases improvement may come after considerably more than a month. Should an operation be undertaken? If there is no approximation to binocular vision it is immaterial when an operation for advancement is performed, and in most cases it is better to wait till the child is old enough to have it performed under local and not general anæsthesia. Is it worth while to try stereoscopic training? If there is rudimentary binocular vision this may be considered, but it must be understood that it is somewhat tedious and cannot be easily carried out at home. At some hospitals special clinics have been established where specially constructed stereoscopes and "cheiroscopes" are adapted to the needs of particular children and used to train the power of binocular vision. The cheiroscope is an invention of Dr. E. E. Maddox, by means of which the child's interest is kept up by having to use his hand as well as his eyes. This sort of treatment has never been so systematically attempted as it is at the present day, but it is still in the experimental stage, and in most cases calls for a large number of visits to the clinic. Selected cases only are suitable, and the length of treatment necessary may be judged by the fact that whereas the number of patients treated in 12 months at the Westminster Hospital was 81, the total number of attendances was 3366. In some cases the treatment can best be carried out in conjunction with operation.

HEALTH AND SOCIAL EVOLUTION.

FROM the Halley Stewart lectures for 1930[1] by Sir George Newman we obtain a valuable survey of the development of our hygienic system. From 1738 to 1790 John Wesley went up and down this country with tireless industry and devotion. Neither before nor since has there been a man who taught so many people for so long. And in whatever theological mould he happened to cast his words, he taught *them three things*: that each individual must have a sense of personal social responsibility; that they must bear one another's burdens; and that no doctrine or belief is worth talking about which does not influence character and prescribe conduct. On a similar ground-work public health has evolved in this country. Such we take to be the text of the admirable sermons preached by a lively practical idealist as Halley Stewart lectures and they discharge excellently well the object of the trust which is "for research towards the Christian ideal in all social life." Sir George Newman gives a fine summary of the results which our hygienic system has achieved by that curious combination of exceptional individual effort and the growth of a sense of collective humanism which most great movements show. And he ends with the wise words of Lord Morley: "Progress depends on the room left by the State for the enterprise, energy, and initiative of the individual."

[1] London: George Allen and Unwin, Ltd. Pp. 200. 4s. 6d.

the general report that the stools of persons harbouring hookworms are not highly coloured, though he notes *that there appears to be no means by which the amount* of fæcal blood can be estimated, and that the conclusion that their colour shows that they do not contain blood is assumption. Some light was however thrown on this point by G. Duncan Whyte,[3] who reported 16 years ago from Swatow, China, that when there was rigorous abstention from meat for 72 hours (and meat must include cockles in this locality), evidence of blood could be obtained in fæces when fewer than 20 worms were afterwards recovered. The test used was an alkaline solution of phenolphthalein with hydrogen peroxide, and it was claimed that it would detect one part of blood in 800,000. Seeing that Looss reared *A. duodenale* to full growth in pups, it should be possible to resolve the doubts expressed by Wells as to whether these figures can be applied to the hookworms of man. Seeing the close resemblance in size and structure between *A. caninum* and *A. duodenale* it will be surprising if they cannot; but in the meantime few medical men will be disposed to question the wisdom of refusing to accept as immaterial to the host these "light" hookworm infections, particularly as the validity of the tests which have been held to exonerate them is not universally accepted.

Moreover in instances where the passage of blood through the gut of hookworms has been slow, by the time it reaches the anal end the hæmoglobin has been reduced, so that whatever constituent of blood is of most value to it as food the host's hæmoglobin serves to supply the hookworm with oxygen. Further, a hookworm deprived of blood by detaching it from the mucosa becomes very sluggish, and in the one instance investigated ceased to oviposit. Yet if when replaced it is still vigorous enough to start feeding it rapidly regains its normal activities. It is not unlikely, then, that unsatisfactory nutrition of the worms, due to that poor quality of the host's blood which is the usual accompaniment of a heavy infection, may be a factor in bringing about that lessening of individual fertility which, as Clayton Lane showed,[4] accompanied increase in the hookworm load in those cases where reports were full enough for this matter to be tested. These ingenious experiments have attacked the hookworm problem from a new and promising angle.

ELECTROCARDIOGRAPHIC DIAGNOSIS OF MYOCARDIAL INFARCTION.

THERE are certain changes in the electrocardiogram that are almost pathognomonic of myocardial infarction—namely, well-marked deviation and rounding of the R–T segment, associated with low voltage ventricular complexes, and as a later development the disappearance of the R–T changes and appearance of a V-shaped T wave, either upright or inverted, and often of considerable amplitude. But the time of appearance and disappearance of these changes is variable, and it is possible for a normal curve to be obtained from a patient with myocardial infarction at two stages of the process: first in the earliest stage, and secondly some time after its occurrence. C. W. Holland and S. A. Levine[5] have studied the time relations of the electrocardiographic changes in 328 cases of coronary occlusion. Only 35 of these gave tracings at any time which could be regarded as normal in all respects. Eight were normal in the first few days after the attack, and the authors record the persistence of a normal curve up to a maximum period of ten days. A second group of 19 cases consisted of those from which characteristic curves followed by normal ones were obtained; a return to normal in one of them within four days illustrates how fleeting the changes may be. Finally there were nine who gave no abnormal curves whatever, although multiple tracings were not always taken. From these and other observations we may conclude that the electrocardiogram is undoubtedly of first importance in the diagnosis of myocardial infarction, but like every other means of investigation cannot be relied on exclusively. If a tracing taken from a patient in the early stages of an attack which presents the clinical features of myocardial infarction proves to be normal this is not nearly as strong evidence against the diagnosis as two or more normal curves taken at intervals of two or three days. On the other hand the finding of a normal curve a month or *more after an attack cannot be taken as* evidence that this was not due to coronary occlusion.

TUBERCULOUS MENINGITIS CURED BY DEEP X RAY THERAPY.

FROM time to time cases of tuberculous meningitis with recovery have been reported, but the total number is small and no satisfactory conclusions about the treatment of this terrible affection have hitherto been possible. Prof. Z. von Bókay,[1] of Debreczen in Hungary, now modestly reports success in five proved cases treated with deep X rays between May and August, 1931. It must be the first time that any one person has seen this number of recoveries and the results demand close scrutiny. The ages of the five patients were 12, 6, 4½, 3, and 3 years and the diagnoses were confirmed either by the finding of tubercle bacilli in the cerebro-spinal fluid or by the positive result of inoculating of the fluid into a guinea-pig. In one case, where bacilli had not been found in the fluid, recovery was so rapid after radiotherapy that the diagnosis of meningism was made, but five weeks later the post-mortem examination of an inoculated guinea-pig showed that the cerebrospinal fluid had been tuberculous. The irradiation employed is described as follows: 162 kilovolts, 4 milliamperes with 0·25 of zinc and up to 3 mm. of aluminium filter, 150–200 R. units with a focal distance of 34 cm. This was applied to the base of the neck, forehead, and temporal regions, the exact situation irradiated varying slightly. Three to four applications were made in each case, with one to two days between the first two, and three to four days between subsequent applications. Recovery, where it took place, seems always to have been complete, a noteworthy feature being the rapid gain in weight as the meningitic symptoms disappeared. Loss of hair appeared to be the only deleterious result of the irradiation and it is possible that the alopecia produced may be permanent, although in one case hair was beginning to grow again over the bald areas a few days after the child left hospital. A more serious possibility is the subsequent development of hydrocephalus or mental deficiency, and it is too soon to say whether Bókay's patients will escape these sequelæ. Moreover, during the months in which these five cases were treated successfully there were elve similar cases in the hospital in which X rays lled completely. Discussing the question of what ctors make for success Bókay emphasises the fact at from a pathological point of view, tuberculosis ay be present either as a diffuse exudative process fecting all the meninges or as a local collection of berculous material in some portion of the meninges. he latter condition is closely allied to the "leaking berculoma" seen in older children and adults who ve survived the presence of tubercle bacilli in the rebro-spinal fluid; and many of the reported cures" of tuberculous meningitis have been thought come into this class. It is impossible to decide e exact pathological lesion in Bókay's cases, but e clinical details given in his paper leave little oubt that they were genuine examples of tuberulous meningitis. This, of course, is often part f a generalised miliary process throughout the body nd, where this is so, cure within the skull cannot be xpected to save the child. Nevertheless, whatever he pathological condition, the cause of death is an ncreasing intracranial pressure and Bókay's point s that if this can be arrested a step forward has een made. The dosage of X rays employed is ery big, but in such a condition as tuberculous neningitis he holds that the *non nocere* principle an be justifiably abandoned and that intensive rradiation of the brain should be carried out without lelay. There are many hundreds of fatal cases of uberculous meningitis in this country every year, and here should be no difficulty in putting the new treatment to an early test.

NON-OPERATIVE TREATMENT OF SQUINT.

FOUR years ago[1] a new department was installed at the Royal Westminster Ophthalmic Hospital to deal with cases of incipient squint, and Mr. Montague L. Hine, in a recent paper,[2] gives a useful summary of the routine treatment as practised there. This treatment is directed to the ordinary cases of concomitant internal squint, not to the paralytic cases which are comparatively uncommon. The criterion for concomitancy is that the angle of deviation remains the same in whatever direction the eyes are looking. Its presence commonly depends on a defective fusion-sense or, as Mr. Hine expresses it, a defect in the degree of development of the inherent desire to use the eyes together, which is a normal instinct in mankind. Acting along with this there is often some upset of the normal relationship between accommodation and convergence or a measurable inequality between the refraction of the two eyes. These are the factors which can be remedied by spectacles. There may also be some lack of balance in the pull of the external muscles of the eyeball, not amounting to paralysis. Appropriate treatment depends on the age of the child. Under 18 months of age a squint, if only occasional, may be neglected; if constant, the fundus should be examined to exclude obvious causes of defective sight such as congenital coloboma or old scars of birth hæmorrhages. If it is concluded that the squinting eye ought to possess useful vision, an effort should be made to occlude the good eye for a time so as to avoid the amblyopia resulting from suppression of the image in the squinting eye. Over the age of 18 months it will be found possible in most cases for children to wear glasses when found desirable after retinoscopy under atropine. At this age small errors of astigmatism may be disregarded. When a squint is persistent and does not alternate, any further loss of vision may be prevented by continuing to occlude the fixing eye. In some cases atropine in the good eye may be sufficient to cause the originally squinting eye to fix.

For school-children who are being treated in the ordinary way by glasses and occlusion or atropinisation of the fixing eye, should this treatment prove insufficient the questions arise: for how long should the occlusion be continued? In cases where the squinting eye is nearly blind, if there is no improvement after a month either the occlusion has been inefficient or else the attempt to improve the vision of the squinting eye is hopeless; in other cases improvement may come after considerably more than a month. Should an operation be undertaken? If there is no approximation to binocular vision it is immaterial when an operation for advancement is performed, and in most cases it is better to wait till the child is old enough to have it performed under local and not general anæsthesia. Is it worth while to try stereoscopic training? If there is rudimentary binocular vision this may be considered, but it must be understood that it is somewhat tedious and cannot be easily carried out at home. At some hospitals special clinics have been established where specially constructed stereoscopes and "cheiroscopes" are adapted to the needs of particular children and used to train the power of binocular vision. The cheiroscope is an invention of Dr. E. E. Maddox, by means of which the child's interest is kept up by having to use his hand as well as his eyes. This sort of treatment has never been so systematically attempted as it is at the present day, but it is still in the experimental stage, and in most cases calls for a large number of visits to the clinic. Selected cases only are suitable, and the length of treatment necessary may be judged by the fact that whereas the number of patients treated in 12 months at the Westminster Hospital was 81, the total number of attendances was 3366. In some cases the treatment can best be carried out in conjunction with operation.

HEALTH AND SOCIAL EVOLUTION.

Finally there were nine who gave no abnormal curves whatever, although multiple tracings were not always taken. From these and other observations we may conclude that the electrocardiogram is undoubtedly of first importance in the diagnosis of myocardial infarction, but like every other means of investigation cannot be relied on exclusively. If a tracing taken from a patient in the early stages of an attack which presents the clinical features of myocardial infarction proves to be normal this is not nearly as strong evidence against the diagnosis as two or more normal curves taken at intervals of two or three days. On the other hand the finding of a normal curve a month or *more after an attack cannot be taken as* evidence that this was not due to coronary occlusion.

TUBERCULOUS MENINGITIS CURED BY DEEP X RAY THERAPY.

FROM time to time cases of tuberculous meningitis with recovery have been reported, but the total number is small and no satisfactory conclusions about the treatment of this terrible affection have hitherto been possible. Prof. Z. von Bókay,[1] of Debreczen in Hungary, now modestly reports success in five proved cases treated with deep X rays between May and August, 1931. It must be the first time that any one person has seen this number of recoveries and the results demand close scrutiny. The ages of the five patients were 12, 6, 4½, 3, and 3 years and the diagnoses were confirmed either by the finding of tubercle bacilli in the cerebro-spinal fluid or by the positive result of inoculating of the fluid into a guinea-pig. In one case, where bacilli had not been found in the fluid, recovery was so rapid after radiotherapy that the diagnosis of meningism was made, but five weeks later the post-mortem examination of an inoculated guinea-pig showed that the cerebrospinal fluid had been tuberculous. The irradiation employed is described as follows: 162 kilovolts, 4 milliamperes with 0·25 of zinc and up to 3 mm. of aluminium filter, 150–200 R. units with a focal distance of 34 cm. This was applied to the base of the neck, forehead, and temporal regions, the exact situation irradiated varying slightly. Three to four applications were made in each case, with one to two days between the first two, and three to four days between subsequent applications. Recovery, where it took place, seems always to have been complete, a noteworthy feature being the rapid gain in weight as the meningitic symptoms disappeared. Loss of hair appeared to be the only deleterious result of the irradiation and it is possible that the alopecia produced may be permanent, although in one case hair was beginning to grow again over the bald areas a few days after the child left hospital. A more serious possibility is the subsequent development of hydrocephalus or mental deficiency, and it is too soon to say whether Bókay's patients will escape these sequelæ. Moreover, during the months in which these five cases were treated successfully there were siculitis on rectal examination; for even with oss visual and tactile examination there is a striking fficulty in recognising a pathological specimen. e variations in the thickness of a vesicle appear depend on functional and neurogenous factors ther than infiltrative lesions. The most reliable oss criteria of the probable presence of chronic minal vesiculitis are found in the prostatic urethra. f 66 specimens showing microscopical evidence of ostatitis, in 49 there was evidence of a greater or ss degree of inflammation of the ejaculatory ducts, ree showing no seminal vesiculitis, 30 showing ight indefinite chronic catarrhal seminal vesiculitis, nd 16 showing marked chronic, subacute, and cute seminal vesiculitis. No considerable inflamation of the vesicles was seen in the absence of orresponding inflammation of the ejaculatory duct. he studies show that the ejaculatory ducts are lways involved in posterior urethral inflammation, ut this seldom results in chronic infiltrative change f the terminal portion of the duct and there is a iminishing tendency toward such involvement as he vesicles are approached.

THE PRIME MINISTER'S EYESIGHT.

IT is announced, through a bulletin signed by Sir Thomas Horder and Mr. Duke Elder, that the condition of the Prime Minister's right eye, which had improved after the rest which followed the operation upon the left eye, is not satisfactory. The normal advice would be that the patient should have a further complete respite from work, but Mr. Ramsay Macdonald's presence at Geneva has been sanctioned with the understanding that he is subjected to as little strain as possible and that three consecutive hours of every day should be given up to complete relaxation. The Prime Minister will be accompanied to Geneva by Sir Thomas Horder and Mr. Duke Elder, which is a wise procedure in the circumstances. A national call can justify the departure from what is the obviously prudent behaviour of a patient in the Premier's situation, but to have expert supervision during the period of trial is more than wise—it is a called-for precaution.

MEDICAL BATHS FOR THE PEOPLE.

THIS country has led the way in the public provision of cleansing baths. At a meeting of the Society of Medical Officers of Health held last week, Dr. R. Fortescue Fox showed how these municipal baths, especially in the cities, might be utilised for medical purposes. Many of them are, as he said, installed in very fine and commodious buildings and have an ample supply of hot and cold water; and while this may lack the unique value of natural medicinal water it should be possible to provide the more useful of the multifarious combinations of heat and movement that constitute the armamentarium of hydrotherapy. Such things, that is, as manipulation pools and baths; fango, in half baths and packs; vapour, with frictions and switchings; salt baths, and re-education. Many local authorities have compiled schemes for the provision of all or some of these measures, but in only quite a few progressive towns have establishments actually been founded. Medical baths are, of course, of little use except under skilled supervision, and—as Dr. G. R. Bruce stated at the same meeting—are only one link in a chain which includes accurate diagnosis, removal of focal infection, and other physical treatment. A municipality willing to provide efficient medical supervision might, Dr. Fox thinks, induce a young graduate interested in such work to specialise in it, allowing him perhaps a year's special training. As medical officer of a bath clinic he would not only supervise hydrotherapy but undertake scientific investigation into swimming and recreational bathing. Dr. Killick Millard, the President, remarked that local authorities had an excellent opportunity to provide rheumatism centres or bathing establishments in their recently acquired general hospitals.

INFANTILE CONVULSIONS.

ALTHOUGH it is recognised that convulsions are much commoner in infancy than at any other time of life, the reason for this is far from clear. It has been suggested that the unstable and immature nervous system of infants reacts in this extreme way to slight peripheral irritation, but this theory has obvious fallacies, one of which is that severe irritation is not accompanied by convulsions. A striking feature of the metabolism of infants, when compared with that of adults, is the lability of the calcium level of the blood, which is readily upset. Fever is known to affect the acid-base balance of the blood with consequent decrease in the ionic blood calcium. Dr. Stanley Graham[1] believes that convulsions in infancy—apart from organic nervous disease—are often if not always due to a lowering of the blood calcium resulting in increased irritability of the nervous system. On this theory he regards convulsions as a form of tetany, and in a study of the seasonal incidence of convulsions appearing at the onset of infections he finds that the incidence curve runs parallel with that of frank tetany, being highest in the dark winter months and falling in the summer. An obvious criticism of this is that infections of the respiratory tract, which are one of the commonest infections met with in infancy, are themselves more common during the winter. Although the convulsion itself appears to cause the disappearance of the usual signs of tetany, such as those described by Trousseau and Chvostek, Graham says that these signs may sometimes be found a day or two after the convulsion. In support of the theory Dr. Noah Morris[2] states that he has found a lowered blood calcium in many cases of infantile convulsions, even in the absence of any clinical or radiological evidence of rickets. At the same time it must be remembered that very low blood calcium values have been found in children who have never shown any convulsive tendency, which suggests that there must be also some other factor which influences the onset of convulsions. For the control of the actual convulsions Graham finds chloral hydrate in doses of grs. 2 to 4 by mouth or grs. 5 per rectum of the greatest benefit; its effect is rapid and lasts longer than that of chloroform. The dose may be repeated two-hourly if necessary and the treatment must not be stopped when the convulsions cease; instead, the quantity of chloral given should be gradually reduced, the intervals being lengthened until only gr. ½ is being taken twice a day. Having controlled the attack and excluded as far as possible any organic nervous disease one should give calcium chloride grs. 15 to 30 four-hourly for three days. This is said to cause a rapid rise in the blood calcium. It is important to prescribe the chloride and not the lactate, for its action is held to depend on its acid-producing property and not on the calcium. Cod-liver oil may also be administered with the idea of improving the absorption of calcium from the bowel.

CHARLES DARWIN.

LAST Tuesday marked the fiftieth anniversary of the death of Charles Darwin. The mid-Victorian era was so gorgeously rich in the production of men of science whose work made history, that these anniversaries must now happen with considerable frequency, while such other anniversaries are claiming attention as birth centenaries or the centenaries or jubilee dates, not of the great discoverer, but of the great discovery. However pious the journalistic intention, it is clear that considerable restraint will have to be exercised in chronicling these numerous recurrencies, but in all scientific circles a personal note on Darwin, if topical, will always be justified. Darwin died on April 19th, 1882, at a ripe old age, twenty-three years after the publication of the work with which his name will always be associated, "The Origin of Species by Means of Natural Selection." The work owed its success to its intrinsic merits, to its carefully selected details, and its judiciously stated and temperate arguments. The logic of the conclusions in certain directions was challenged at the time, and new knowledge has placed certain of their implications in a different perspective, but he remains the typical man of science whose theories, entrenched behind a bulwark of facts, revolutionised much modern thought; and he will be an everlasting example of devotion to learning.

AVERTIN IN THE TROPICS AND ELSEWHERE.

THE use of anæsthetics in the tropics is beset with difficulties peculiar to the atmospheric and the racial conditions in which they must be administered. It is asserted, for instance, that the evaporation rate of ether is so affected that one ounce which takes 20 minutes to evaporate at an English seaside resort in July takes, in similar conditions, 5 minutes in Bombay in the hot season and 11 minutes at Singapore. Writing from his experiences at Singapore Dr. A. Barnsley [1] states that ether from an open mask, although a far more effective anæsthetic in Malaya than in India, still suffers from the moisture with which the atmosphere is saturated. Chloroform he finds, in accordance with general experience, is attended with "an appalling relative mortality." Nitrous oxide and oxygen is not available except in the larger centres, and is here circumscribed in application because of its expense. To superstitious and uneducated people the ritual of inhalation anæsthesia is alarming, and Dr. Barnsley has welcomed the introduction of avertin into practice in the tropics. He believes that, "if used with reasonable care and in suitable cases, it will increase the efficiency of tropical surgery a hundredfold," and has found it highly satisfactory in his own experience. The fall of blood pressure which may occur under avertin influence has been subjected to careful observation by G. W. Taylor and C. C. Lund.[2] They find that usually the clinical state of the patient gives no intimation of the marked drop which may have taken place, the ratio of pulse pressure to diastolic pressure showing little alteration. Occasionally, however, the patient showed a weak rapid pulse, depressed shallow respirations, pallor, and cyanosis. In such cases the response to a single dose of ephedrine has been prompt, and there was no tendency for a second drop after its effect had worn off. Taylor and Lund conclude that the drop of blood pressure which they have observed is independent of surgical shock because the venous oxygen figure in these cases is always within normal limits, and it has been shown that in shock the venous oxygen content is greatly reduced. It may be noted here that E. Desmarest[3] of the Hôpital Ambroise-Paré in Paris, is much impressed by the value of the combination of avertin and nitrous oxide and oxygen, finding that the inhalation of the latter effectually combats the drop of blood pressure which may arise from the former. Also he maintains that any respiratory depression due to avertin injection is easily controlled with inhalation of nitrous oxide and oxygen, the oxygen being increased or curtailed in accordance with the patient's needs and carbon dioxide introduced with the inhalation when effective respiratory stimulation is required.

THE SEMINAL VESICLES.

Two papers on the vesiculi seminales read at the annual meeting of the American Medical Association last year have now been published [4]—both of them contributed from the department of urology of the New York Post-graduate Medical School. The first, by J. F. McCarthy and J. S. Ritter, deals especially with the clinical aspect. The writers point out that in part of their course the two ejaculatory ducts are separated by no more than a very thin septum and so it has happened that the passage of a No. 4 ureteral catheter, followed by the injection of opaque medium, has resulted in a vesiculogram of the opposite side. The duct of the seminal vesicle is a direct continuation of the ejaculatory duct, whereas the ampulla of the vas is a tributary; thus a catheter may enter the former but not the latter. R. S. Roper [5] has indicated difficulties in catheterising the ejaculatory ducts, but McCarthy, since the introduction of his instrument in 1925, has found it possible to perform this operation in most cases. It will be recalled that a year ago Frank Kidd [6] reported that he had catheterised the ejaculatory ducts with this instrument in eight cases. Now that such catheterisation is possible vesiculograms can be taken, fluid from the vesicles uncontaminated by prostatic secretion can be obtained for examination, vesicular lavage can be carried out, and the ducts can be dilated in order to improve drainage. Kidd, however, believed that after some years' further experience it will be found that disinfection of the vesicles can be more readily and safely accomplished by Belfield's open vasotomy than by washing out the vesicles from below. McCarthy and Ritter have not noted any definite changes in the appearance of the vesicles referable to the various decades of life. On discussing the findings in 50 cases in which the vesicles were examined two interesting complications of enlargement of these structures are mentioned, one being ureteral obstruction giving rise to colic, and the other acute urinary retention. In taking vesiculograms the only complications, noted in a small proportion of cases, were subacute epididymitis, which rapidly subsided, and occasionally leakage of sodium iodide into surrounding structures, causing severe pain for a few minutes but no subsequent trouble. In the second paper, by J. A. Hyams, S. E. Kramer, and McCarthy, an important point brought out is the clinical difficulty of diagnosing chronic seminal siculitis on rectal examination; for even with oss visual and tactile examination there is a striking fficulty in recognising a pathological specimen. ie variations in the thickness of a vesicle appear depend on functional and neurogenous factors ther than infiltrative lesions. The most reliable oss criteria of the probable presence of chronic minal vesiculitis are found in the prostatic urethra. f 66 specimens showing microscopical evidence of ostatitis, in 49 there was evidence of a greater or ss degree of inflammation of the ejaculatory ducts, ree showing no seminal vesiculitis. 30 showing ight indefinite chronic catarrhal seminal vesiculitis, ad 16 showing marked chronic, subacute, and cute seminal vesiculitis. No considerable inflammation of the vesicles was seen in the absence of orresponding inflammation of the ejaculatory duct. he studies show that the ejaculatory ducts are lways involved in posterior urethral inflammation, ut this seldom results in chronic infiltrative change f the terminal portion of the duct and there is a diminishing tendency toward such involvement as he vesicles are approached.

THE PRIME MINISTER'S EYESIGHT.

It is announced, through a bulletin signed by Sir Thomas Horder and Mr. Duke Elder, that the condition of the Prime Minister's right eye, which had improved after the rest which followed the operation upon the left eye, is not satisfactory. The normal advice would be that the patient should have a further complete respite from work, but Mr. Ramsay Macdonald's presence at Geneva has been sanctioned with the understanding that he is subjected to as little strain as possible and that three consecutive hours of every day should be given up to complete relaxation. The Prime Minister will be accompanied to Geneva by Sir Thomas Horder and Mr. Duke Elder, which is a wise procedure in the circumstances. A national call can justify the departure from what is the obviously prudent behaviour of a patient in the Premier's situation, but to have expert supervision during the period of trial is more than wise—it is a called-for precaution.

MEDICAL BATHS FOR THE PEOPLE.

This country has led the way in the public provision of cleansing baths. At a meeting of the Society of Medical Officers of Health held last week, Dr. R. Fortescue Fox showed how these municipal baths, especially in the cities, might be utilised for medical purposes. Many of them are, as he said, installed in very fine and commodious buildings and have an ample supply of hot and cold water; and while this may lack the unique value of natural medicinal water it should be possible to provide the more useful of the multifarious combinations of heat and movement that constitute the armamentarium of hydrotherapy. Such things, that is, as manipulation pools and baths; fango, in half baths and packs; vapour. with frictions and switchings; salt baths, and re-education. Many local authorities have compiled schemes for the provision of all or some of these measures, but in only quite a few progressive towns have establishments actually been founded. Medical baths are, of course, of little use except under skilled supervision. and—as Dr. G. R. Bruce stated at the same meeting—are only one link in a chain which includes accurate diagnosis, removal of focal infection, and other physical treatment. A municipality willing to provide efficient medical supervision might, Dr. Fox thinks, induce a young graduate interested in such work to specialise in it, allowing him perhaps a year's special training. As medical officer of a bath clinic he would not only supervise hydrotherapy but undertake scientific investigation into swimming and recreational bathing. Dr. Killick Millard, the President, remarked that local authorities had an excellent opportunity to provide rheumatism centres or bathing establishments in their recently acquired general hospitals.

INFANTILE CONVULSIONS.

Although it is recognised that convulsions are much commoner in infancy than at any other time of life, the reason for this is far from clear. It has been suggested that the unstable and immature nervous system of infants reacts in this extreme way to slight peripheral irritation, but this theory has obvious fallacies, one of which is that severe irritation is not accompanied by convulsions. A striking feature of the metabolism of infants, when compared with that of adults, is the lability of the calcium level of the blood, which is readily upset. Fever is known to affect the acid-base balance of the blood with consequent decrease in the ionic blood calcium. Dr. Stanley Graham[1] believes that convulsions in infancy—apart from organic nervous disease—are often if not always due to a lowering of the blood calcium resulting in increased irritability of the nervous system. On this theory he regards convulsions as a form of tetany, and in a study of the seasonal incidence of convulsions appearing at the onset of infections he finds that the incidence curve runs parallel with that of frank tetany, being highest in the dark winter months and falling in the summer. An obvious criticism of this is that infections of the respiratory tract, which are one of the commonest infections met with in infancy, are themselves more common during the winter. Although the convulsion itself appears to cause the disappearance of the usual signs of tetany, such as those described by Trousseau and Chvostek, Graham says that these signs may sometimes be found a day or two after the convulsion. In support of the theory Dr. Noah Morris[2] states that he has found a lowered blood calcium in many cases of infantile convulsions, even in the absence of any clinical or radiological evidence of rickets. At the same time it must be remembered that very low blood calcium values have been found in children who have never shown any convulsive tendency, which suggests that there must be also some other factor which influences the onset of convulsions. For the control of the actual convulsions Graham finds chloral hydrate in doses of grs. 2 to 4 by mouth or grs. 5 per rectum of the greatest benefit; its effect is rapid and lasts longer than that of chloroform. The dose may be repeated two-hourly if necessary and the treatment must not be stopped when the convulsions cease; instead, the quantity of chloral given should be gradually reduced, the intervals being lengthened until only gr. ½ is being taken twice a day. Having controlled the attack and excluded as far as possible any organic nervous disease one should give calcium chloride grs. 15 to 30 four-hourly for three days. This is said to cause a rapid rise in the blood calcium. It is important to prescribe the chloride and not the lactate, for its action is held to depend on its acid-producing property and not on the calcium. Cod-liver oil may also be administered with the idea of improving the absorption of calcium from the bowel.

CHARLES DARWIN.

LAST Tuesday marked the fiftieth anniversary of the death of Charles Darwin. The mid-Victorian era was so gorgeously rich in the production of men of science whose work made history, that these anniversaries must now happen with considerable frequency, while such other anniversaries are claiming attention as birth centenaries or the centenaries or jubilee dates, not of the great discoverer, but of the great discovery. However pious the journalistic intention, it is clear that considerable restraint will have to be exercised in chronicling these numerous recurrencies, but in all scientific circles a personal note on Darwin, if topical, will always be justified. Darwin died on April 19th, 1882, at a ripe old age, twenty-three years after the publication of the work with which his name will always be associated, "The Origin of Species by Means of Natural Selection." The work owed its success to its intrinsic merits, to its carefully selected details, and its judiciously stated and temperate arguments. The logic of the conclusions in certain directions was challenged at the time, and new knowledge has placed certain of their implications in a different perspective, but he remains the typical man of science whose theories, entrenched behind a bulwark of facts, revolutionised much modern thought; and he will be an everlasting example of devotion to learning.

AVERTIN IN THE TROPICS AND ELSEWHERE.

THE use of anæsthetics in the tropics is beset with difficulties peculiar to the atmospheric and the racial conditions in which they must be administered. It is asserted, for instance, that the evaporation rate of ether is so affected that one ounce which takes 20 minutes to evaporate at an English seaside resort in July takes, in similar conditions, 5 minutes in Bombay in the hot season and 11 minutes at Singapore. Writing from his experiences at Singapore Dr. A. Barnsley [1] states that ether from an open mask, although a far more effective anæsthetic in Malaya than in India, still suffers from the moisture with which the atmosphere is saturated. Chloroform he finds, in accordance with general experience, is attended with "an appalling relative mortality." Nitrous oxide and oxygen is not available except in the larger centres, and is here circumscribed in application because of its expense. To superstitious and uneducated people the ritual of inhalation anæsthesia is alarming, and Dr. Barnsley has welcomed the introduction of avertin into practice in the tropics. He believes that, "if used with reasonable care and in suitable cases, it will increase the efficiency of tropical surgery a hundredfold," and has found it highly satisfactory in his own experience. The fall of blood pressure which may occur under avertin influence has been subjected to careful observation by G. W. Taylor and C. C. Lund.[2] They find that usually the clinical state of the patient gives no intimation of the marked drop which may have taken place, the ratio of pulse pressure to diastolic pressure showing little alteration. Occasionally, however, the patient showed a weak rapid pulse, depressed shallow respirations, pallor, and cyanosis. In such cases the response to a single dose of ephedrine has been prompt, and there was no tendency for a second drop after its effect had worn off. Taylor and Lund conclude that the drop of blood pressure which they have observed is independent of surgical shock because the venous oxygen figure in these cases is always within normal limits, and it has been shown that in shock the venous oxygen content is greatly reduced. It may be noted here that E. Desmarest[3] of the Hôpital Ambroise-Paré in Paris, is much impressed by the value of the combination of avertin and nitrous oxide and oxygen, finding that the inhalation of the latter effectually combats the drop of blood pressure which may arise from the former. Also he maintains that any respiratory depression due to avertin injection is easily controlled with inhalation of nitrous oxide and oxygen, the oxygen being increased or curtailed in accordance with the patient's needs and carbon dioxide introduced with the inhalation when effective respiratory stimulation is required.

THE SEMINAL VESICLES.

Two papers on the vesiculi seminales read at the annual meeting of the American Medical Association last year have now been published[4]—both of them contributed from the department of urology of the New York Post-graduate Medical School. The first, by J. F. McCarthy and J. S. Ritter, deals especially with the clinical aspect. The writers point out that in part of their course the two ejaculatory ducts are separated by no more than a very thin septum and so it has happened that the passage of a No. 4 ureteral catheter, followed by the injection of opaque medium, has resulted in a vesiculogram of the opposite side. The duct of the seminal vesicle is a direct continuation of the ejaculatory duct, whereas the ampulla of the vas is a tributary; thus a catheter may enter the former but not the latter. R. S. Roper[5] has indicated difficulties in catheterising the ejaculatory ducts, but McCarthy, since the introduction of his instrument in 1925, has found it possible to perform the operation in most cases. It will be recalled that a year ago Frank Kidd[6] reported that he had catheterised the ejaculatory ducts with this instrument in eight cases. Now that such catheterisation is possible vesiculograms can be taken, fluid from the vesicles uncontaminated by prostatic secretion can be obtained for examination, vesicular lavage can be carried out, and the ducts can be dilated in order to improve drainage. Kidd, however, believed that after some years' further experience it will be found that disinfection of the vesicles can be more readily and safely accomplished by Belfield's open vasotomy than by washing out the vesicles from below. McCarthy and Ritter have not noted any definite changes in the appearance of the vesicles referable to the various decades of life. On discussing the findings in 50 cases in which the vesicles were examined two interesting complications of enlargement of these structures are mentioned, one being ureteral obstruction giving rise to colic, and the other acute urinary retention. In taking vesiculograms the only complications, noted in a small proportion of cases, were subacute epididymitis, which rapidly subsided, and occasionally leakage of sodium iodide into surrounding structures, causing severe pain for a few minutes but no subsequent trouble. In the second paper, by J. A. Hyams, S. E. Kramer, and McCarthy, an important point brought out is the clinical difficulty of diagnosing chronic seminal

THE MINIMUM COST OF YSIOLOGICALLY ADEQUATE DIETS FOR WORKING-CLASS FAMILIES.

By G. P. Crowden, M.Sc., M.R.C.S. Eng.,
TURER IN INDUSTRIAL PHYSIOLOGY, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

IMPORTANCE OF PROPER NUTRITION.

There is good reason to believe that proper trition is the most important condition for the aintenance of health and efficiency. Food is the imary factor which determines the state of nutrition men, women, and children. Hence it is of paraount importance to the national health that penditure on items other than food in family dgets should not render it impossible for families ith small fixed incomes per week to provide out of come an adequate diet for the family.

The terrible consequences to national health sulting from food shortage and improper food were ident in Germany in the later stages of and immeiately after the war, as reported on by Prof. Starling 1919.[1] To-day, in England, individual families ay suffer just as much owing to unsound family onomics and bad household management, coupled ith a lack of knowledge of what constitutes an dequate, well-balanced diet.

As in Germany during and after the war it was ot the "breadwinner" who suffered most, so too o-day the mother and the children are the ones ainly affected. If it were not for the many voluntary id organisations, the existence of malnutrition would e much more in evidence. Even so, the figures or 1930[2] published by the Chief Medical Officer o the Board of Education reveal the fact that in ,739,297 medical inspections of children of school ge, 29,876 children were found to be suffering from alnutrition.

Table I.—*Expenditure Per Man-value Per Week.*

Notes.	Food.	Rent.	Clothing.	Fuel.	Other items.	Total all items.
Board of Trade, 1904, distribution of weekly expenditure in working-class families ..	60 %	16 %	12 %	8 %	4 %	100
Ministry of Labour indices of cost for January, 1932; 1914 prices taken as 100	131	154	190	175	175	147
Distribution of weekly expenditure January, 1932; 1904 figures corrected for 1932 indices of cost..	53 %	17 %	16 %	9 %	5 %	100
Weekly budget based on 7/– January, 1932, cost of adequate food per man-value per week	7/–	2/2	2/0½	1/3	7½	13/1

MINIMUM COST OF PROPER FOOD PER WEEK.

Information has been collected from various sources in order to determine the minimum cost of providing an adequate, well-balanced, varied, and physiologically sound diet per unit man-value per week, and, with this figure as a basis, the minimum cost of adequate food per week for families of varying size has been calculated. The sum of 7/– per week per man-value appears to be the absolute minimum of expenditure on food under the best possible conditions of household management and economic purchasing by the mother at the present time.

The Board of Trade inquiry in 1904 furnished data in regard to the distribution of expenditure between the various items which make up the weekly budgets of working-class families. The Cost of Living Index[3] is calculated on this distribution of the weekly income using the 1914 prices of commodities as the basis. Table I. shows the weekly expenditure per unit man-value as calculated from the Cost of Living figures for January, 1932, published by the Ministry of Labour.[4]

WEEKLY BUDGETS.

Table II. shows the weekly budgets of families of man-value 1·5 to 4·5. This table gives figures for the minimum cost of adequate food for such families based on the rate of 7/– per man-value per week. The expenditure on rent and other items in the weekly budget is calculated from the Cost of Living indices and the Board of Trade figures for the distribution of family expenditure shown in Table I.

Table II.—*Family Budgets Based on the Cost of Living Data of the Ministry of Labour and the Minimum Cost of Adequate Food at January, 1932, Price Levels.*

Family man-value.	Minimum cost of food per week.	Rent.	Clothing.	Fuel.	Other items.	Minimum weekly income per family.
1·5	10/6	3/3	3/0¾	1/10½	11¼	19/7½
2	14/–	4/4	4/1	2/6	1/3	26/2
2·5	17/6	5/5	5/1¼	3/1½	1/6¾	32/8½
3	21/0	6/6	6/1½	3/9	1/10½	39/3
3·5	24/6	7/7	7/1¾	4/4½	2/2¼	45/9½
4	28/0	8/8	8/2	5/0	2/6	52/4
4·5	31/6	9/9	9/2¼	5/7½	2/9¾	58/10½

The right-hand column in Table II. gives what appears to be the minimum weekly income which these families need at the present time, assuming that the basis on which the present Cost of Living Index is calculated is a sound one. On the other hand, if the present-day standard of living demands that a substantially greater percentage of working-class family income shall be spent on rent than it did in 1904, then these minimum weekly income figures are too small, while the amount which needs must be spent on food remains the same, for it is based on the physiological needs per man-value and current retail prices.

Owing to collective agreements for the periodical adjustment of wage rates in accordance with the variations in the Cost of Living Index figure, the data published by the Ministry of Labour do affect the incomes of a large number of working-class families, hence it is reasonable to compare actual present-day family budgets with the theoretically economic budgets calculated from such data and shown in Table II.

EXPENDITURE ON RENT.

In a number of family budgets examined by Miss M. L. Clark and Miss M. Hetherington, the proportion of weekly income spent on rent is widely different from 17 per cent., and the expenditure on rent alone, which presumably must be paid, renders it absolutely impossible for some of these families to purchase a physiologically adequate diet even on the basis of the minimum figure of 7/– per man-value per week for food. This figure of 7/– per man-value per week presupposes the most economic purchasing and household management by the mother in the family—an assumption which is rarely justified.

AN OPHTHALMIC DYNASTY.

THE death of Hermann Pagenstecher, at the age of 87, recalls a family that has become not only a German national institution, but almost a national industry, for Wiesbaden, where the Pagenstechers practise as ophthalmic surgeons, draws patients not only from Germany but from remote countries. The ophthalmic tradition of the family goes back to Karl Pagenstecher (1824–65), a general practitioner who made a great reputation as an oculist and shares with Donders the honour of describing ocular paralyses in diphtheria. But it was Alexander Pagenstecher who established the ascendancy of the family. An intensely practical man with exceptionally dexterous fingers, he rose rapidly in Wiesbaden where he settled in 1853, doing at first both general practice and ophthalmic work. He had laid a good basis for his work by studying under the great masters of the day; he had worked with Desmarres and Sichel in Paris, with Bowman and Critchett in London, and it was Graefe who had persuaded him to take up ophthalmology. Four years after settling in Wiesbaden he opened a small public clinic for eye diseases, and within a few years this had grown to a famous eye hospital which attracted as students men whose names later became household words in ophthalmology: Theodore Saemisch, Mandelstamm, Berlin, Iwanoff; and two members of the Pagenstecher family, Arnold and Hermann Pagenstecher, Alexander's brother, helped to increase the rising reputation of the hospital by a series of contributions published in the reports of the institution. The death of Alexander Pagenstecher in 1879, at the age of 51, from injuries received by the accidental discharge of a rifle, removed a figure that had become almost legendary. Endless stories of his skill were told and his name was known in every ophthalmic clinic owing to the remarkable vogue of an ointment that passed under his name—yellow oxide of mercury specially prepared for ophthalmic use to eliminate irritating by-products. Probably all the preparations of mercuric oxide used to-day are the descendants of Pagenstecher's ointment, though of course the substance itself has a great antiquity in medicine. The great practical achievement of Alexander Pagenstecher was, however, the elaboration, together with his brother and successor Hermann, of the intracapsular method of cataract extraction. This was, and still is, the only radical departure from the method of cataract extraction described by Daviel in 1751.

Hermann Pagenstecher, though no less a craftsman than his brother, had contributed more widely to ophthalmic literature, his chief contribution being an Atlas of Pathological Anatomy, published in 1875, of which he was a joint author. Sixteen years younger than Alexander, he directed the institution his brother had built up, till 1901 when his son Adolf took charge of it. But the call on his skill never abated. Queen Victoria and the Empress Frederick were amongst his distinguished clientèle. His beautiful hands and slender fingers seemed to perform miracles of operative skill. Heavily hit by the war and the subsequent financial collapse in Central Europe, he continued to practise, and even operate during the past few years. A man of great kindliness and simplicity he was dearly beloved by his patients, and the hardship of recent years was mitigated for him by a substantial sum collected from his English patients and friends by the late Mr. Howard Hodgkin and the late Lady Courtney. Arnold Pagenstecher (1837–1913), a pupil and nephew of Karl Pagenstecher, was another member of this family to carry on the ophthalmic tradition, whilst the work at Wiesbaden is still being continued by Adolf Pagenstecher, the present director of the Eye Hospital.

Ophthalmology has a remarkably large number of dynasties. Direct continuity of father and son occurs a number of times: Snellen, Coppez, Van Duyse, Fuchs, Landolt, Lagrange, von Scily, and Green abroad, Guthrie and Lang in this country, are examples of famous fathers and sons. The fathers must have been trebly blessed; they had sons after their own hearts—and hands and eyes.

A LAY ADMINISTRATIVE OFFICER.

THE Manchester city council has now confirmed the appointment of Mr. George Ogden to the newly created post of lay administrative officer. The post owes its establishment to the very great development of the work of the public health department during the past two or three years. The transfer of the poor-law medical services in itself has more than doubled this work—indeed, perhaps, trebled it from the administrative point of view. All the institutions as well as the hospitals are in the charge of the public health committee, which also controls the district medical service, vaccination, infant life protection, and all matters relating to hospital or medical work formerly carried out by the guardians. Before the transfer of the poor-law medical services, the hospital beds under the control of the committee numbered just over 1000, while now there are considerably over 9000. The new officer is appointed to deal with the lay administrative work for the whole of the department, subject to the medical officer of health. He is entrusted as part of his duties with the special duty of supervising expenditure at, and in connexion with, the various hospitals and institutions, and of advising the medical officer from time to time on economies which it might be possible to bring about. It is particularly hoped that this administrative supervision will effect definite economies in the purchase of food and materials of all kinds, and will further improve the efficiency in the lay staffing of the department, more especially in the larger establishments. There is no doubt, in the opinion of the medical officer of health, that this appointment is a step in the right direction, since much of his time in the past has been taken up by matters which ought to be easily and effectively decided by an officer of the type now appointed. He will thus be left freer for the consideration of administrative policy and development and for the study of those problems which are most important in the application of preventive medicine.

Mr. Ogden, who is 43 years of age, has hitherto been principal administrative clerk in the Manchester public health department. His appointment carries a salary of £1000 a year.

Sir William Watson Cheyne, who has died on April 19th, in his eightieth year, was a great figure from the time when he became Lister's prominent lieutenant in the revolution of surgery. He held the chair of surgery in King's College, London, was President of the Royal College of Surgeons of England, an F.R.S., and surgeon in ordinary to the King. For a period he represented Scottish universities in the House of Commons.

THE MINIMUM COST OF PHYSIOLOGICALLY ADEQUATE DIETS FOR WORKING-CLASS FAMILIES.

By G. P. Crowden, M.Sc., M.R.C.S. Eng.,
LECTURER IN INDUSTRIAL PHYSIOLOGY, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

IMPORTANCE OF PROPER NUTRITION.

There is good reason to believe that proper nutrition is the most important condition for the maintenance of health and efficiency. Food is the primary factor which determines the state of nutrition of men, women, and children. Hence it is of paramount importance to the national health that expenditure on items other than food in family budgets should not render it impossible for families with small fixed incomes per week to provide out of income an adequate diet for the family.

The terrible consequences to national health resulting from food shortage and improper food were evident in Germany in the later stages of and immediately after the war, as reported on by Prof. Starling in 1919.[1] To-day, in England, individual families may suffer just as much owing to unsound family economics and bad household management, coupled with a lack of knowledge of what constitutes an adequate, well-balanced diet.

As in Germany during and after the war it was not the "breadwinner" who suffered most, so too to-day the mother and the children are the ones mainly affected. If it were not for the many voluntary aid organisations, the existence of malnutrition would be much more in evidence. Even so, the figures for 1930[2] published by the Chief Medical Officer to the Board of Education reveal the fact that in 2,739,297 medical inspections of children of school age, 29,876 children were found to be suffering from malnutrition.

Table I.—*Expenditure Per Man-value Per Week.*

Notes.	Food.	Rent.	Clothing.	Fuel.	Other items.	Total all items.
Board of Trade, 1904, distribution of weekly expenditure in working-class families ..	60%	16%	12%	8%	4%	100
Ministry of Labour indices of cost for January, 1932; 1914 prices taken as 100	131	154	190	175	175	147
Distribution of weekly expenditure January, 1932; 1904 figures corrected for 1932 indices of cost..	53%	17%	16%	9%	5%	100
Weekly budget based on 7/- January, 1932, cost of adequate food per man-value per week	7/-	2/2	2/0½	1/3	7½	13/1

MINIMUM COST OF PROPER FOOD PER WEEK.

Information has been collected from various sources in order to determine the minimum cost of providing an adequate, well-balanced, varied, and physiologically sound diet per unit man-value per week, and, with this figure as a basis, the minimum cost of adequate food per week for families of varying size has been calculated. The sum of 7/- per week per man-value appears to be the absolute minimum of expenditure on food under the best possible conditions of household management and economic purchasing by the mother at the present time.

The Board of Trade inquiry in 1904 furnished data in regard to the distribution of expenditure between the various items which make up the weekly budgets of working-class families. The Cost of Living Index[3] is calculated on this distribution of the weekly income using the 1914 prices of commodities as the basis. Table I. shows the weekly expenditure per unit man-value as calculated from the Cost of Living figures for January, 1932, published by the Ministry of Labour.[4]

WEEKLY BUDGETS.

Table II. shows the weekly budgets of families of man-value 1·5 to 4·5. This table gives figures for the minimum cost of adequate food for such families based on the rate of 7/- per man-value per week. The expenditure on rent and other items in the weekly budget is calculated from the Cost of Living indices and the Board of Trade figures for the distribution of family expenditure shown in Table I.

Table II.—*Family Budgets Based on the Cost of Living Data of the Ministry of Labour and the Minimum Cost of Adequate Food at January, 1932, Price Levels.*

Family man-value.	Minimum cost of food per week.	Rent.	Clothing.	Fuel.	Other items.	Minimum weekly income per family.
1·5	10/6	3/3	3/0¾	1/10½	11¼	19/7½
2	14/-	4/4	4/1	2/6	1/3	26/2
2·5	17/6	5/5	5/1¼	3/1½	1/6¾	32/8½
3	21/0	6/6	6/1½	3/9	1/10½	39/3
3·5	24/6	7/7	7/1¾	4/4½	2/2¼	45/9½
4	28/0	8/8	8/2	5/0	2/6	52/4
4·5	31/6	9/9	9/2¼	5/7½	2/9¾	58/10½

The right-hand column in Table II. gives what appears to be the minimum weekly income which these families need at the present time, assuming that the basis on which the present Cost of Living Index is calculated is a sound one. On the other hand, if the present-day standard of living demands that a substantially greater percentage of working-class family income shall be spent on rent than it did in 1904, then these minimum weekly income figures are too small, while the amount which needs must be spent on food remains the same, for it is based on the physiological needs per man-value and current retail prices.

Owing to collective agreements for the periodical adjustment of wage rates in accordance with the variations in the Cost of Living Index figure, the data published by the Ministry of Labour do affect the incomes of a large number of working-class families, hence it is reasonable to compare actual present-day family budgets with the theoretically economic budgets calculated from such data and shown in Table II.

EXPENDITURE ON RENT.

In a number of family budgets examined by Miss M. L. Clark and Miss M. Hetherington, the proportion of weekly income spent on rent is widely different from 17 per cent., and the expenditure on rent alone, which presumably must be paid, renders it absolutely impossible for some of these families to purchase a physiologically adequate diet even on the basis of the minimum figure of 7/- per man-value per week for food. This figure of 7/- per man-value per week presupposes the most economic purchasing and household management by the mother in the family—an assumption which is rarely justified.

Schedule A shows that an adequate well-mixed diet can be purchased at the cost of approximately 7/– per man-value per week. The list of foodstuffs was compiled by the Mothers' Committee of the North Islington Welfare Centre in July, 1929, when the index for food stood at 150. The cost of food per unit man-value per week at that time was 8/2½. By January, 1932, the index for the cost of food had fallen to 131, which reduces the weekly cost per man-value to approximately 7/–.

The quantities of food purchased for the week according to this schedule are for a family of man, wife, and three children, aged, 8, 6, and 3, which according to the Cathcart scale [5] of Family Coefficients shown in Table III. has an equivalent man-value of 3·53.

TABLE III.—*Family Coefficients (Cathcart Scale).*

Man	1·00	Child, 8–10 (9 11/12ths.)	0·7
Woman	0·83	,, 6– 8 (7 11/12ths.)	0·6
Boy, 14 + ...	1·00	,, 3– 6 (5 11/12ths.)	0·5
Girl, 14 + ...	0·83	,, 2– 3 (2 11/12ths.)	0·4
Child, 12–14 (13 11/12ths.)	0·9	,, 1– 2 (1 11/12ths.)	0·3
,, 10–12 (11 11/12ths.)	0·8	,, 0– 1 (11/12ths.) ..	0·2

The dietary is varied, well balanced, adequate in calories, and includes a sufficiency of vitamin-containing foodstuffs, fresh milk, butter, vegetables, and fruits. In calories and proportion of protein, fat, and carbohydrate this dietary is very similar to the diet for the average man adopted by the Royal Society Food (War) Committee.[6]

LONDON FAMILY BUDGETS.

Schedule B gives a few examples of family budgets collected in London, together with the theoretically economic budget for each family according to the man-value as calculated from Table II.

In the case of Family No. 1, the man was a sailor and did not live at home, but allowed his wife 32/6 per week to keep herself and three children, aged 10, 6, and 5, having a man-value of 2·73. At 7/– per man-value per week this family needed 19/1 for food alone, yet they were committed to a weekly rent of

* Employed ; † unemployed. Med.= medicines.

6, which left 19/– to cover food, clothing, fuel, other items, such as washing and cleaning. This nily, according to the scale shown in Table II., uld have paid 5/11 for rent instead of 13/6, and s spending 41·5 per cent. of the weekly income on t as compared with 17 per cent., which presumably a fair proportion for a family of this status. The penditure on food was 28 per cent. less than that cessary to purchase a physiologically adequate etary.

In Family No. 2 the man was a casual labourer the docks, earning 30/– per week. The rent paid s 13/6, which left 16/6 for the family for the week, though according to the man-value of 2·93, 20/6 as the minimum amount necessary for food alone. he family spent nothing on fuel, clothes, or other ems, and was in debt 5/8 at the end of the week. ch a man could not possibly do his heavy muscular ork without adequate food, and the expenditure 45 per cent. of his weekly income on rent made ebt inevitable.

Two budgets are shown for Family No. 3, the first hen the man was employed and the second when he as on unemployment relief. The rent of 10/– was 2 per cent. more than this family could afford, and he money spent on food was 47 per cent. less than he minimum necessary expenditure. I understand hat the wife has now broken down in health.

Family No. 4 shows a more satisfactory budget. he expenditure on food is substantially the amount heoretically essential according to the scale shown n Table II. Rent represents 23·9 per cent. of the eekly income, as compared with 17 per cent. calcuated on the Cost of Living data, but this expenditure on rent is reasonable, for in this family it did not entail the cutting down of essential expenditure on ood.

The number of family budgets quoted in Schedule B is, of course, too small from which to draw any general conclusions, but in so far as they are the actual budgets of working-class families in receipt of very limited incomes, it is worthy of note that the mean weekly expenditure on rent amounted to 34·7 per cent. of the total weekly income, or twice the percentage of 17, on which the Ministry of Labour bases its present calculation of the Cost of Living Index.

If a family undertakes such a fixed weekly commitment as rent, and then finds by bitter experience that insufficient money is left for the provision of adequate food, on the physiological minimum basis of 7/– per man-value per week, it is inevitable that debt or breakdown in health or both will follow.

EDUCATIONAL AND ADMINISTRATIVE ACTION.

It appears, therefore, that some educational and administrative action should be taken to prevent such family misfortunes, or at least warn the working-class public against such probabilities. There is little doubt that welfare and social workers could interest mothers in family budgets if they had at their disposal such data as shown in Table II. above. They could easily work out the minimum cost of food per family per week and tell the mother what money she should set aside for the purpose, and what amount should reasonably be allowed for rent and other items, but it must be made quite clear that food must be the first consideration in deciding whether any increased fixed weekly commitment, such as the rent of a new house, is justified.

I feel sure that some administrative measures are also desirable because families may be anxious to take new houses, and be allowed to commit themselves to weekly rentals or instalments which render the proper feeding of the family an economic impossibility.

The need for proper food and the minimum cost of adequate food should be clearly understood. Whatever may be the urgency for housing undertakings paying their way, it is in bad business from the national health point of view if such can only be achieved at the expense of family health.

Officials, whose duty it is to let council or other dwellings, should be conversant with some such scale as Table II., and on inquiry from a prospective tenant as to his weekly income and size of family, be prepared to say whether or not such a fixed weekly commitment as the rent or instalment on the particular dwelling is justified. It should be the recognised duty of such an official to refuse to let a dwelling unless he is satisfied that the weekly rental will not make it impossible for the family to purchase adequate food on the basis of 7/– per man-value per week. Moreover, sufficient money to cover reasonable expenditure on other items such as clothes and fuel must remain after deducting the cost of food and rent from the weekly income.

No doubt further inquiry in London and elsewhere will be needed before the necessary measures can be taken, but in the interests of the health of the working-class community it is essential that such inquiries should be followed by educational and administrative action.

MEDICINE AND THE LAW.

Unregistered Practitioner and Death Certification.

"WHAT exactly does this registration as a medical practitioner mean?" The asking of this question by the foreman of a coroner's jury shows how widespread is the popular ignorance as to the relative powers and qualifications of registered and unregistered practitioners.

The Craven coroner, Mr. E. Wood, was holding an inquest at Barnoldswick, Lancs, in a case where the deceased having been attended by an unregistered practitioner, no death certificate was forthcoming. The deceased, a woman 40 years of age, was attended last November by a registered practitioner, Dr. J. W. Pickard. On Feb. 12th, being ill again, she called in an unregistered doctor practising at Preston. He visited her again on the 17th and 19th; on this last date the patient's husband decided to call in Dr. Pickard again; the unregistered doctor was informed of the intention and apparently approved. Dr. Pickard attended the patient on the 19th and found her very weak, "having a certain amount of pyrexia and seeming to be very dazed." He called again on the 21st; according to the husband, Dr. Pickard did not then see the patient as she was asleep; he told the husband that, if the unregistered doctor was going to attend the patient, he could not himself do so. The unregistered doctor attended her on the [illegible] *knowing that she had been attended by an unregistered practitioner." It was at this point that the foreman asked his question about the meaning of registration. Dr. Pickard, in answer, briefly explained the system of medical education, qualification, and registration under the supervision of the General Medical Council.*

Earlier in the proceedings the husband had stated that his wife had special confidence in the unregistered doctor and would not have called anyone else in had he always been available. The coroner explained that, however able this doctor might be, he could not issue a death certificate; "the public must understand that in the event of death an inquiry must take place." No registered practitioner, the coroner added, will attend a patient if he knows that an unregistered doctor is called in. "I am not holding a *brief for* [illegible] but Dr. Pickard would not have *been justified* [illegible] death certificate *in this case." The* [illegible] have given *useful publicity to* [illegible] abilities *of the unregistered* [illegible] *sign a death certificate* [illegible] *suppose that the public* [illegible] *would desire the* [illegible]

[illegible]

[illegible]OLOGY

[illegible]

The [illegible] of the two sections was [illegible] Dr. [illegible] into existence [illegible] in loco parentis. [illegible] be regarded as [illegible] he liked to remember [illegible] meant by derivation [illegible] enough until the morning! He had never known an affair of twins proceed more smoothly and expeditiously or with less anxiety to the official watcher. The new sections owed much to the wise and unobtrusive leadership of the two presidents and to the spirit of mutual coöperation manifested by the Council and by the general body of members of the old sections, who had not hesitated to [illegible] the "old bottles" when it had become obvious that they would not hold the "new wine." He entertained the most optimistic view of the prospects of the new sections. Physical medicine was a time-honoured branch of medical work—witness the [illegible]logical treatment at Bethesda—while radiology [illegible] bright young thing of modern medicine [illegible] med to him a particularly favourable [illegible] the apostles of physical methods [illegible] ved in a drug-ridden age and [illegible] did not exactly advise [illegible] the dogs," it did undertake [illegible] of proclaiming the healing [illegible] ature. The most striking [illegible] the phenomenal rapidity [illegible] otography were fulfilled [illegible] ere is nothing covered [illegible] It was hardly too [illegible] now held almost the [illegible] urgery in fee, [illegible] e would hope that [illegible] ealing the emotions [illegible] adium and X rays [illegible] be determined [illegible] radiotherapeutic [illegible] ons of the [illegible] nce that [illegible] een [illegible] tions. Treatment by physical methods was as as mankind, while radiology had a history but thirty-seven years. He dreamed of the day en practitioners in both branches of medicine uld have full opportunity of advancing their rk by clinical teaching, perhaps even in special spitals. The object of the two sections was to omote intensive study, and progress was best ieved through clinical teaching.

The health of the guests was proposed by . THOMSON, who stressed the part played and e influence exerted by Dr. Watts Eden in promoting e smooth and uneventful arrival of the two new tions. His attitude throughout had been aracterised by the kindly solicitude and confident timism which were valuable assets on anxious casions. The name of Sir Robert Jones was known l over the world, and largely owing to his achieve-ents and energy the science of orthopædics had en raised from being the happy hunting-ground of educated bone-setters to what was perhaps the ost progressive branch of surgery to-day. r. Edwards, the Secretary of the Society, had en guide, philosopher, and friend, and might be scribed as the "silent gear-box" of the Society— d a preselective gear at that. Finally, Dr. Thomson elcomed the presence at the dinner of so many dies, who were naturally attracted by sections ill in their infancy.

Sir ROBERT JONES, in reply, wished every success the two new sections and the Society and was onfident that in giving his good wishes he was etting on a certainty. As he understood that a azz-band in the near vicinity was whetting its nstruments of torture, and as he firmly believed in cientific manipulation of the limbs for the develop-ent of the health of the body, he declined to keep hem any longer from health-giving exercise.

A large number of the guests then went to the all-room placed at their disposal by the management.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

WORK OF THE LOCAL APPOINTMENTS COMMISSION.

IT will be remembered that under the authority of the Local Authorities (Officers and Employees) Act, 1926, local authorities are bound to appoint o offices in their service only such persons as have een recommended to them for the purpose by a ntral body, the Appointments Commission. In ch case the Appointments Commission nominates person to be appointed, so that in effect the ointments rest with the Commission and not with local authorities. The Commission normally on the advice of a selection board, which is made l hoc for each appointment or group of appoint- s of a similar nature, of persons with special dge of the duties to be performed. As regards appointments it is recognised by everyone quality of the candidates for such offices of dispensary medical officer has materially d since the present system was established. candidates formerly were wont to rely n their local and family influences, they now that qualifications and evidence of experience important. As a result, the public medical are attracting a better class of candidates than formerly. In 1928, after some two years' experience of the working of the Act, the Dáil nominated a select committee to inquire and report whether any amendment of the Act was desirable. In February, 1930, the committee submitted its report, which contained several recommendations; some suggesting minor amendments of the Act, and others merely changes in procedure. The recommendations had the general approval of the medical profession, and some disappointment has been caused by the fact that no action was taken on the report. With a change of Government it is hoped that the report may now receive consideration. A rumour, however, is being circulated in the press to the effect that the present Government are considering altering the Act in an important particular. It is said that it is proposed to provide that the Appointments Commission should forward three names instead of one in each case to the local authority, the final choice to rest with the latter. Medical opinion is definitely against such a proposal, which is regarded as retrograde. It is pointed out that the local authority is not competent, as are the selection board, to estimate the value of professional qualifications and experience, and in so far as a local authority exercises any choice it is likely to be influenced by considerations which should be extraneous. Moreover, the general tendency of all the reforms in the public medical services in recent years has been toward centralisation, and toward making a transition to a State service easy. To restore the power which was taken from the local authorities six years ago is a reversal of this tendency.

HONORARY FELLOWS OF THE ROYAL COLLEGE OF PHYSICIANS OF IRELAND.

Last Saturday evening the two recently elected honorary Fellows of the Royal College of Physicians of Ireland were admitted to the College by the President, Prof. T. G. Moorhead. They are Sir Almroth Wright, F.R.S., and Mr. Edward Stephenson, chief medical adviser to the Department of Local Government and Public Health of the Irish Free State. After the ceremony of admission the President of the College, who is also President of the Royal Academy of Medicine in Ireland, entertained a large number of the Fellows of both bodies and several distinguished guests to dinner.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE.

THE following appointments are notified: Surg. Lt.-Cmdr. H. W. Strong to *Pembroke* for Gt. Yarmouth Hospital. Surg. Lts. G. A. Miller to *Stuart* and *Kempenfelt*; J. G. Currie to *Rodney*; E. H. Rampling to *Renown*; W. W. Simkins to *Douglas*; and F. W. A. Fosbery to *Ladybird*.

Surg. Lt.-Comdrs. (D). F. W. Watt to *Malaya* and T. Hunt to *Effingham II.*; Surg. Lt. (D). F. J. Goldsworthy to *Ganges*.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt. W. F. Lascelles to be Surg. Lt.-Comdr.

R.A.M.C.: TERRITORIAL ARMY.

Lt. A. A. Eagger to be Capt.

Supernumerary for service with the O.T.C.—Maj. C. H. Budd to be Lt.-Col., and to comd. the Med. Unit, Cambridge Univ. Contgt., Sen. Div., O.T.C.

INDIAN MEDICAL SERVICE.

Capt. G. C. Phipps, from R.A.M.C., with seniority, to be Capt.

Lt.-Col. S. W. Jones retires.

R.A.F. RESERVE OF AIR FORCE OFFICERS.

Flight-Lt. J. J. Clarke is transferred from Class D (ii) to D (i).

20th and 21st; on the 22nd she died. Asked by the coroner at the inquest to express an opinion as to the cause of death, Dr. Pickard said that, having heard the reports of the county analyst (who had analysed the medicines administered to the patient) and of the county pathologist, he was prepared to suggest the cause as "heart failure resulting from exhaustion due to menopausal mania." He did not think her life could have been saved. The foreman of the jury asked Dr. Pickard whether he would have given a death certificate if he had known that a local doctor had been called in. The witness replied, "if I had known sufficient of her and what medicine she had been given, I should have been ble to give a certificate; as I understand the law, should not have been entitled to give a certificate knowing that she had been attended by an unregistered practitioner." It was at this point that the foreman asked his question about the meaning of registration. Dr. Pickard, in answer, briefly explained the system of medical education, qualification, and registration under the supervision of the General Medical Council.

Earlier in the proceedings the husband had stated that his wife had special confidence in the unregistered doctor and would not have called anyone else in had he always been available. The coroner explained that, however able this doctor might be, he could not issue a death certificate; "the public must understand that in the event of death an inquiry must take place." No registered practitioner, the coroner added, will attend a patient if he knows that an unregistered doctor is called in. "I am not holding a brief for either side, but Dr. Pickard would not have been justified in giving a death certificate in this case." These proceedings will have given useful publicity to one of the very few disabilities of the unregistered doctor, namely, his inability to sign a death certificate. There is no reason to suppose that the public, when the point is appreciated, would desire the law to be changed.

Tobacco Blindness.

At the Liverpool Assizes lately an acetylene welder sued his former employers for damages for personal injuries alleged to be caused by their negligence or breach of duty. The plaintiff complained that he suffered from nicotine poisoning as a result of welding plates on to moulds which had been used in tobacco factories and that his eyesight was temporarily affected. In support of the claim a civil engineer stated that in rewelding the tobacco moulds the application of an oxyacetylene welder would volatilise the nicotine and produce noxious fumes. The defendants contended that the tobacco blindness was due to excessive smoking and had nothing to do with the man's employment.

The jury awarded the plaintiff £35, a result with which Mr. Justice Charles said he profoundly disagreed. He deferred judgment in order to consider which scale of costs should be allowed, but subsequently he awarded costs on the High Court scale. The defendants, he said, had treated the claim from the beginning as a matter of importance and dealt with it as a High Court case, calling witnesses of high distinction in support of their contention. Presumably the learned judge meant that this course committed the plaintiff to corresponding effort, but it seems hard that the defendants should be penalised for having obtained expert assistance in resisting a claim with which the judge himself clearly had little sympathy.

PHYSICAL MEDICINE AND RADIOLOGY:

A JOINT CELEBRATION.

A COMBINED dinner of the Sections of Physical Medicine and Radiology of the Royal Society of Medicine was held at Claridge's Hotel, London, on Friday, April 15th. The dinner was in celebration of the formation of these two sections last autumn, and the chair was taken in dual form by Dr. F. G. Thomson, President of the Section of Physical Medicine, and Prof. J. M. Woodburn Morison, President of the Section of Radiology. The guests of honour were Dr. T. Watts Eden, President of the Society, and Sir Robert Jones, who had delivered an address (reported on p. 885 of this issue) to the Section of Physical Medicine at its meeting earlier in the evening.

The health of the two sections was proposed by Dr. WATTS EDEN, who said that, as they had come into existence during his presidency, he stood to them in loco parentis. If he could more appropriately be regarded as having presided over their birth, he liked to remember that the word "obstetrician" meant by derivation "one who stood by"—often enough until the morning! He had never known an affair of twins proceed more smoothly and expeditiously or with less anxiety to the official watcher. The new sections owed much to the wise and unobtrusive leadership of the two presidents and to the spirit of mutual coöperation manifested both by the Council and by the general body of members of the old sections, who had not hesitated to scrap the "old bottles" when it had become obvious that they would not hold the "new wine." He entertained the most optimistic view of the prospects of the new sections. Physical medicine was a time-honoured branch of medical work—witness the balneological treatment at Bethesda—while radiology was the bright young thing of modern medicine. The present seemed to him a particularly favourable opportunity for the apostles of physical methods of treatment. We lived in a drug-ridden age and, while physical medicine did not exactly advise us to "throw physic to the dogs," it did undertake the all-important mission of proclaiming the healing virtues which resided in Nature. The most striking thing about radiology was the phenomenal rapidity of its growth. In radiophotography were fulfilled the prophetic words: "There is nothing covered that shall not be revealed." It was hardly too much to say that radiology had held almost the whole field of medicine and surgery in fee, save perhaps, psychiatry—and everyone would hope that radiologists would stop short of revealing the emotions. He submitted that the position of radium and X rays as therapeutic agents had yet to be determined, and assumed that the position of radiotherapeutics would be one of the chief preoccupations of the new section. And he reminded the audience that the triumphant march of radiology has been secured at the cost of the lives of men who had counted those lives as of little worth in comparison with the advancement of their science.

Prof. WOODBURN MORISON, in reply, welcom steady progress made in physical medicin radiology and the full recognition accorded l Royal Society of Medicine to the changes tha resulted. The two new sections had much in co and already they ranked twelfth and thirteent the strength of their membership, among tl illi which are found in these children's stomach-tents human or bovine? Dr. Collis has not yet ed his cases. Does the presence of tubercle illi in stomach contents in cases of erythema dosum necessarily prove that pulmonary tuberosis also is present? Dr. Collis tells me that his cases there is X ray evidence of this in the gs, but in his letter he hesitated to label these ildren as suffering from pulmonary tuberculosis.

One of the points of my article was to show that must not confuse pulmonary tuberculous *infection*, ich may be frequent and benign, with pulmonary berculous *disease*, which is rare and grave. I ink here Dr. Collis and I are on common ground, d I agree with him that the boundary between the o conditions may have to be defined. In conasion may I remind Dr. Collis that he is working here the most rare conditions in children are mmonplace; while house physician in the same spital some years ago I had the opportunity of serving a new case of congenital hypertrophy of e pylorus approximately every week; yet to the ulk of the profession this condition also must main a medical curiosity.

I am, Sir, yours faithfully,

F. J. BENTLEY.

TOXIC EFFECTS OF PHENOLPHTHALEIN.

To the Editor of THE LANCET.

SIR,—I have read with interest in your issue of pril 9th (p. 803) Dr. Phillipps's letter on the toxic ffects of phenolphthalein, and the numbers of perient proprietary preparations which now contain t. It is often a matter of extreme difficulty for the kin specialist who probably sees the most cases of oxic eruptions to elucidate the cause, and as new preparations are being constantly put on the market and prescribed it is a practical impossibility to be acquainted with all of them, and to have a knowledge of their ingredients.

I have records of three cases in which I ascribed the symptoms to the presence of phenolphthalein in a trade preparation. In one of these the toxic symptoms were as acute as Dr. Phillipps describes in his own case. This patient, a woman of 65, came on a visit to her daughter after an operation for removal of the breasts. Two days after her arrival she developed an acute erythematous and œdematous eruption, involving mainly the neck and upper part of the trunk. The itching was excessive, and her discomfort intense. As she was a Jewess of strictly orthodox type, the diet was naturally suspect; it was carefully investigated, without result. No medicines were being taken, except pil. alophen., which her surgeon had advised when an aperient was needed. She had taken this pill after her arrival. On suspension of the drug the symptoms rapidly responded to treatment. Pil. alophen. contains phenolphthalein, and though I had not previously diagnosed a case of phenolphthalein poisoning, I ascribed the symptoms in this case to its use.

In the other two cases the toxic effects were not so extreme as in this case, but as the symptoms were relieved on cessation of the drug they seemed clear cases of cause and effect. One of the cases had been ordered pil. alophen., the second case a paraffin preparation containing phenolphthalein. In both the main symptom was excessive itching, and in one case the irritation was so severe that she had produced numbers of sores by scratching. The eruption was difficult to define in these cases, as it varied in type, showing occasionally small ill-defined erythematous patches, or a few scattered papules lichenoid in type. Both were women of over 60 years of age, and the cases are of interest in view of the large number of cases in which pruritus is the main symptom, and for which no cause can be discovered.

I am, Sir, yours faithfully,

London, W., April 14th. ELIZABETH HUNT, M.D.

PSYCHOLOGY AND MEDICINE.

To the Editor of THE LANCET.

SIR,—In an interesting review of Dr. Alfred Adler's latest book in your last week's issue, the writer, who conceals his identity not too impenetrably under the initials F. G. C., claims Prof. Einstein as an adherent of Adler's system of individual psychology while quoting his bon mot that Adler is the Sancho Panza to Freud's Don Quixote. Now this epigram was the reply which Einstein gave to my question what he thought of Freud and of Adler, at Oxford last summer, when we were dining together at Christ Church. He also expressed the view as regards Freud's theory of infantile sexuality that "life couldn't be so complicated as all that." But he hastened to add that he could not speak with any authority on these matters as he had no special scientific acquaintance with the underlying facts. Here spoke the man of science, for it is really impossible to decide the validity of the claims of these contending schools of psychology without a wide experience of the facts, gained by patient and prolonged analyses of individual cases.

It is my own experience, after prolonged and deep analyses of many cases of psychoneurosis, that both theories, each in its own sphere, illuminate the results, and that a satisfactory explanation can only be gained if both points of view are retained. But this involves the rejection of much of the explanatory detail of each, and the incorporation of ideas from the recognised teachings of academic psychologists such as Ward, James, McDougall, Myers, and others. In other words, all these investigators are to be regarded as separate and original contributors to one single science, the science of psychology. Such a view is not eclecticism (a word that only has meaning, and a bad one, in philosophy), but the generally accepted view as to the nature of all genuine sciences.

If, on the other hand, psycho-analysis and individual psychology are set over against one another as mutually incompatible schemes of psychological thought, their fate will be that of the Kilkenny cats, and general psychology will have to get along without them. I am, Sir, yours faithfully,

Harley-street, W., April 16th, 1932. WILLIAM BROWN.

"LOW-SEGMENT" CÆSAREAN SECTION.

To the Editor of THE LANCET.

SIR,—Your second leading article of last week is entitled Low-segment Cæsarean Section. That operation has been called by many names, but is not this new one apt to lead to confusion? Lower segment is the term which has been used for generations and should, I think, still be used, since some operators make the incision for the classical operation low down in the upper segment—for example, Mrs. Ivens-Knowles, whose excellent results you give, though

CORRESPONDENCE

ECONOMY IN THE PUBLIC HEALTH SERVICES.

To the Editor of THE LANCET.

SIR,—There can be few in the medical profession who do not think that the national spirit of extravagance, now generally admitted, exists in some degree in branches of our social services. There is a tendency for luxuries to be classed as necessities for the public health, and my feeling is that much expenditure might be saved without the public welfare suffering. May I suggest some lines on which economy might be exercised. I will deal first with economy in administration, and then with economy in public health institutions.

In my experience of medical and health administration in peace and war, extending over 20 years or more, I have found a constant tendency (of myself and others) to over-staff. He who desires a reputation for efficiency will staff his office for the maximum amount of work at any period of the year, rather than for the average; not an unnatural tendency, as it contributes to efficiency at all times, freedom from errors, punctuality in returns, and peace in the office. If, however, a compulsory reduction is made, it is often surprising how little reduction in efficiency is noticeable. Reports a shade less elaborate, a little extra work, a little overtime at certain periods, a little less comfort for everybody—but the work is done. That a layman, or committee of laymen, is capable of estimating what the staff should be is, I think, seldom possible. It requires a medical man with experience. Yet it is my experience that the specialist or expert carrying out the duties at the time is not the person who should have the final word as to the number of his staff. In this respect in the Army the arrangements are good, for every specialist has his immediate chief, possibly not an expert but experienced. He can view the specialist's probably not unprejudiced requests with an independent eye and a due sense of proportion. Two other tendencies, which I need not elaborate, contribute to overstaffing: the first is sitting at a desk when one should be visiting the area; the other, the issue of too elaborate returns. Experience, especially in war-time, has shown me that to obtain good results it is not always necessary to have the most expensive apparatus or to follow the most expensive methods. To give a single example, it does not require a large fixed bath to make a man clean, a small tin one would do this as well. I have learnt not to confuse health necessities with luxuries and comforts.

Of institutions I do not claim to have more personal experience than comes to most members of the profession. The opinion of general practitioners on some of them would be instructive. What do they feel about the value of health visitors as a public health institution; does the public get full value for the money spent? And then school medical work; might it not be more practical and possibly less expensive to utilise the general practitioner who is the family doctor as well. At present the school medical officer only sees children at school and rarely when ill; the practitioner does not see them at school and rarely when well? Would not a system by which the children's parents render special certificates drawn up by their own doctor at fixed periods answer as well or better? Take infant welfare centres. At one period when in the Army I had the supervision of several of these. The actual amount allowed for expenditure in a centre was £5 a year; medical officer, nurse (if available), and accommodation cost nothing. A medical inspection room was utilised; failing that, a disused barrack room. Comparison with the expense of civil centres is therefore difficult. Although the comfort of the medical officer may have suffered to some extent by lack of accessories, I doubt if they affected the success of the centre. The personality and ability of the medical officer was indeed the chief factor. It is possible that sometimes the comfort of the staff is overdone; this is not a noticeable failing in the Army.

These are a few of the lines on which economy might be exercised; some others have been mentioned previously in your columns.[1] I do not think that they are exhausted. It may be asked whether there is any constructive idea in my mind. I consider that the medical profession as a whole has not enough share in the administration of public health. apart from the executive work. Laymen are fond of dabbling in public health, some with success, others for various reasons run amuck. Municipalities and county councils in their public health work should be well leavened with general practitioners, whose knowledge, experience, and practical acquaintance with many of the problems arising should make them efficient in checking unnecessary expenditure. Their help too would be invaluable to the health medical officer. But they stand aloof from public health administration.

I am, Sir, yours faithfully,
W. F. TYNDALE, M.D. Lond., D.P.H.

Bishopthorpe, York, April 18th, 1932.

PULMONARY TUBERCULOSIS IN CHILDHOOD.

To the Editor of THE LANCET.

SIR,—It is a pity that Dr. Collis in your issue of April 9th did not explain his point in greater detail. The matter really is one of considerable interest. My article dealt with pulmonary tuberculosis only, and I stated that this disease, associated with tubercle bacilli in the sputum, was rare in children. I also said that this combination was a grave one, few such sufferers surviving at the end of five years. I quoted figures. May I repeat that in the year 1930 only 95 children under 15 years of age were certified as dying from pulmonary tuberculosis in the whole of London. If, as Dr. Collis infers, wider search for the bacilli will demonstrate "a surprising number of positive cases," I, personally, would have expected that deaths would be more numerous than is at present shown by the returns. But Dr. Collis tells me that he thinks pulmonary tuberculosis in which there is either no obvious expectoration or in any event no tubercle bacilli present in it, but in which tubercle bacilli presumably from swallowed sputum are found in the stomach contents, may be not only comparatively common, but benign.

If Dr. Collis can establish the frequency and favourable outlook of such a condition it will be of much interest scientifically, but I do not think it will have any immediate application from a public health point of view; our concern must remain chiefly with the grave disease where tubercle bacilli are found in the sputum, and we need not worry about children who are apparently getting well at present without our aid. But further work needs to be done on this controversial subject. Are the tubercle

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

PUBLIC HEALTH SERVICES.

IN the House of Commons on Tuesday, April 12th, the motion that the Speaker do leave the Chair the House going into Committee of Supply on the il Estimates, and Estimates for the Revenue partments, 1932,

The Medical View.

Dr. MORRIS-JONES moved the following amend-ent:—

> "That this House appreciates the progress made by al authorities since the passing of the Local Government t of 1929 in coördinating and improving their public alth services and, while recognising the need for economy local expenditure, is of opinion that the development these services should steadily continue as and when rumstances permit."

e said the Local Government Act of 1929 in its ope and magnitude, in the vast number of interests hich it touched, and in its effects on the prosperity d well-being of this country, was one of the greatest easures ever passed by that House. The Act had S clauses and voluminous schedules, and the ovisions dealing with the public health services one occupied many pages. One of the big achieve-ents of the Act was the transfer of the poor-law rvices to the present authorities. The new authorities o years ago succeeded in taking over their new ities without failing to relieve any known case of stitution. He questioned if any other country in e world could have achieved such a change in like anner. The main objects of the public health rovisions were to achieve eventually improved and ficient public health services in this country, and the second place to secure economy. Looking ack over the records of the last 40 years he found at expenditure on local administration, which was 36,000,000 in 1891, was to-day close on £300,000,000. nd a very large part of that sum came under the ead of public health. Schemes were supposed to e submitted under the Act of 1929 for the absorption f poor-law institutions. Other institutions were to e altered and made more adaptable to modern onditions. Some were to be declared redundant, nd some were to be used for a different purpose. hat movement was undoubtedly long overdue in he interests of public health. He understood that n the London area very much progress had been nade in dealing with poor-law institutions. He aw from the figures of the last report of the Minister f Health that 37 poor-law institutions had been ppropriated for use as hospitals, and nine of them or use as children's hospitals or convalescent homes.

THE TRANSFERRED HOSPITALS.

The case in the country was far from satisfactory. Only 19 out of 79 county boroughs had submitted schemes for the reclassification of their poor-law nstitutions, and not one county council outside London had been able to appropriate a single poor-law nstitution for the purpose of a general hospital under the control of the local authority. The intention of the 1929 Act was that all local authorities should, as far as possible, provide all the assistance necessary on medical and public health grounds under powers which they possessed under other Acts than the Poor-law Acts. The Local Government Act empowered them to make a declaration that such-and-such health services should be provided otherwise than by way of poor-law relief. Were the local authorities making these declarations? Had any county council or county borough yet transferred the functions of the public assistance committee to the public health committee or to the maternity and child welfare committee? He did not suggest that they should have too much departmentalism in the public service. Medical officers in charge of such services should work as a team. There was permission under the Act for medical officers to consult with the specialists of the large public hospitals. He was afraid that so far not much in the way of consultation was going on. He had no doubt that the tendency of the Ministry of Health was to get whole-time medical officers under their control as far as they could. He was a great believer in the general medical practitioner, and he hoped that the Minister would discourage any tendency to relegate the treatment of disease to officers of the Ministry. Some local authorities were suggesting doing away with the old poor-law medical officer. He would be very sorry if that came about. One or two authorities had suggested that visits to patient's homes should be made by their own institutional medical officer, and one authority had proposed, or had had under consideration, the setting up of a panel something like that under the National Insurance Act whereby a sick person in receipt of parish relief would be able to select any doctor from the panel in the neighbourhood. He did not think that that would lead to efficiency or economy. The old parish doctors contained among their class the ablest and most conscientious general medical practitioners in the country, who regarded it as a privilege and a pride to look after the poor. These doctors were the only medical men in many areas, and they attended both rich and poor. Under the Act a doctor could only be relieved of his office with the consent of the Minister, and he trusted that the Minister would reluctantly give his consent, unless there were medical grounds for doing so.

ECONOMY AND EFFICIENCY.

The second main function of the Act was national economy. He would like to know what effect the crisis of last September and since had had in regard to public health services, and whether the Minister considered that there was a reasonable standard of efficiency and progress maintained without excessive or unreasonable expenditure. While he took the view as a medical man that expenditure on health services must not be curtailed at the cost of efficiency, he also held the view that it must be examined thoroughly in view of the state of the national Exchequer. Looking into the figures of the reductions in rates, for instance, he found that local authorities had been able to arrive at a fictitious reduction in many cases, but that owing to increased assessments the amount actually expended by many local authorities at the present time was greater in 1931–32 than in the previous year. He did not think that the present House of Commons was reactionary in regard to public health. He felt sure that it would support the Minister of Health in any measures that might be required to retain for this country a model public health service.

Lieut.-Colonel FREMANTLE, in seconding Dr. Morris-Jones's amendment, said there were four lines of thought in considering the Local Government Act in these difficult times. First, they were all agreed that they must maintain the efficiency both of their institutions and their personnel. They could not allow any economies to reduce that. In the second place, in view of the necessity for economy, they wished to make better use of the present facilities by reorganisation. In the third place, they ought to revise the traditions or the groove into which administration might have sunk in the light of experience. Fourthly, they wished to advance slowly on an agreed path. They had to face the fact that they could not as yet measure the results of the Local Government Act by any definite figures, although the late Minister of Health and others supporting him tried to measure their efficiency by the decline in the mortality rates. The figures for 1931 were definitely disappointing. That was you wrongly date her book on Cæsarean Section, which was published in 1931. Your article states :—

> "H. R. Spencer has reported 120 cases, many of which were infected before operation, with four deaths. This should be compared with the 1·23 per cent. mortality at the Chicago Lying-in Hospital in 895 cases of the low-segment operation."

May I set out a few facts which render such comparison difficult ? In my little book on Cæsarean Section (1925) I have given in detail every one of my 120 cases of Cæsarean section in hospital and private, over a period of 32 years, from 1892 to 1925 (I have since had one private case, successful to mother and child). The Chicago Lying-in Hospital cases are comparatively recent ; were operated on by many operators, and not all their cases of Cæsarean section are given. In 1925 J. B. de Lee published 136 cases of the classical operation at that hospital, with seven deaths, but he did not give details of the cases. But he did state that in 24 of the cases the wound suppurated. My cases were not discharged before the 24th day ; 59·8 per cent. of the Chicago cases were discharged by the 14th day, one on the 8th. And what about embolism after the lower-segment operation ? Phaneuf reports 80 cases of that operation, with six deaths, and three cases of pulmonary embolism, one of which was fatal. Has embolism ever occurred with such frequency after the classical operation ?

In my book I appealed for a complete and detailed record of cases in order that the relative merits of the classical and the lower-segment operation may be decided. The 895 Chicago cases of lower-segment operation (which is unsuited for the graver cases of cancer and tumours) are no answer to that appeal.—I am, Sir, yours faithfully,

HERBERT R. SPENCER.

Bickenhall Mansions, W., April 16th, 1932.

MARMITE IN SPRUE.

To the Editor of THE LANCET.

SIR,—In your issue of April 16th (p. 829) Dr. Janet M. Vaughan and Dr. Donald Hunter write on marmite in the anæmia of idiopathic steatorrhœa, and (on p. 837) is reported a contribution by Dr. Lucy Wills in the discussion at the Section of Tropical Medicine of the Royal Society of Medicine on the megalocytic anæmias of the tropics. May I recall that in the opening paper of a discussion on the treatment of sprue at the same Society on Dec. 3rd, 1923, I mentioned that I had for long used marmite in the treatment of sprue, nearly always complicated by anæmia, and recorded two cases of severe sprue who gained a pound a day for 14 and 21 days respectively, accompanied by great general improvement, on marmite treatment at the Hospital for Tropical Diseases, London, where I am still using it in such cases. Colonel W. P. Macarthur in the same discussion mentioned that he had independently come to the same conclusion, and B. K. Ashford, of Porto Rico, has also repeatedly laid stress on the importance of an unbalanced diet in predisposing to sprue.

I am, Sir, yours faithfully,

London, April 17th, 1932. LEONARD ROGERS.

ROYAL NORTHERN HOSPITAL.—Last year the in-patients numbered 6162, an increase of 756, and 369 of the 417 beds were in daily occupation. Out-patients' attendances numbered 339,579, an increase of 30,000. The deficiency on the year was just under £3000, as compared with nearly £10,000 in 1930. It has been necessary to close two wards containing 46 beds, the debt now being £121,328, of which over £65,000 is in respect of buildings and equipment. The private patients' wing is entirely self-supporting.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED APRIL 9TH, 1932.

Notifications.—The following cases of infectious disease were notified during the week :—Small-pox 70 (last week 95) ; scarlet fever, 1356 ; diphtheria, 726 ; enteric fever, 12 ; acute pneumonia (primary or influenzal), 1319 ; puerperal fever, 41 ; puerperal pyrexia, 96 ; cerebro-spinal fever, 74 ; acute polio-myelitis, 7 ; encephalitis lethargica, 15 ; dysentery, 13 ; ophthalmia neonatorum, 98. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on April 12th–13th was as follows: Small-pox, 117 under treatment, 6 under observation (last week 121 and 4 respectively) ; scarlet fever, 1419 ; diphtheria, 1390 ; enteric fever, 11 ; measles, 2712 ; whooping-cough, 425 ; puerperal fever, 30 (plus 16 babies) ; encephalitis lethargica, [illegible] "other diseases," 121. At St. [illegible] were 13 babies (plus 6 mothers) [illegible] um.

Deaths.—In 117 great towns, including London, there was no death from small-pox, 3 (1) from enteric fever, 139 (66) from measles, 5 (1) from scarlet fever, 48 (10) from whooping-cough, 22 (6) from diphtheria, 46 (11) from diarrhœa and enteritis under two years, and 114 (19) from influenza. The figures in parentheses are those for London itself.

Dagenham and Willesden reported deaths from enteric fever. No great town reported as many as 10 fatal cases of influenza, Leeds standing highest with 8, and Bristol with 6. Leeds and Liverpool each reported 9 deaths from measles, Manchester 7, and Derby 5 ; but more than two-thirds of the measles deaths occurred in Greater London. There were 4 deaths from whooping-cough at Sunderland and at Birmingham.

The number of stillbirths notified during the week was 342 (corresponding to a rate of 46 per 1000 births), including 47 in London.

MEDICAL NEEDS OF SOUTH AFRICAN NATIVES.

Dr. A. J. Orenstein, president of the Medical Association of South Africa, speaking at the annual meeting of the Bridgman Memorial Hospital for Coloured People at Johannesburg on Feb. 25th, said that the economic position of the bulk of the natives is such that they are unable to pay for the medical attention they require. There had been, he said, talk of a national insurance scheme for natives, but even the relatively small sum which this would cost would be impossible for those in the rural areas, though the condition was slightly better in the towns. Work was done among the natives in the country by district surgeons, who were supposed to attend pauper patients. District surgeons, however, were few and far between, and their remuneration for attendance on paupers devolved on the local authority. The position, in Dr. Orenstein's opinion, is deplorable. At the end of 1926 it was found, in all provinces of the Union, that in the public hospitals there were 1803 beds for the use of natives. Half of these beds were divided among the three cities, and the average was one bed for 2000 persons. A conservative estimate for the needs of natives would be one bed for every 700 persons, and to provide even this low number 4000 additional beds would have to be found for part-paying or non-paying patients, and with capital expenditure and annual cost of maintenance the cost per annum would be roughly £500,000. He suggested an expansion of the existing hospitals, especially those run by private subscription. He also advocated more medical services for rural areas.

GRAND OPERA FOR BIRMINGHAM HOSPITALS.—Arrangements are being made for a week of grand opera at the Prince of Wales's Theatre, Birmingham, for the benefits of the city's principal hospitals. The whole of the scenery, properties, and wardrobes are being lent by the Covent Garden Opera Company. The General, the Queen's, and the Ear and Throat Hospitals will share the profits.

ondon, real coöperation and coordination in the ork of municipal and voluntary hospitals.

Government Reply.

Sir E. Hilton Young (Minister of Health), replying t the debate, said that there had been a resolute tempt to represent that unwise restrictions were ing placed on the public health services in the terests of economy. For that suggestion there was shadow of foundation of any sort or kind. The st argument used in favour of that contention was misquotation of a Circular on economy issued at e time of the national crisis to local authorities. e words of the Circular were :—

> "His Majesty's Government would not contemplate at local authorities should embark on a wholesale and -considered course of cutting down expenditure, whatever its character or purpose. Such a policy seems to them ither necessary nor advisable."

as there in that any reckless disregard of the ficiency of the services in the interests of economy ? urther down in the Circular they found the special servation that consideration was to be given as to hether a service was required on urgent grounds of ublic health. It was the policy of this Government, s it must be the policy of every Government which ad the welfare of the country at heart, to consider ublic health as a matter of urgent national importance nd to regard economy as false which would reduce e efficiency of the essential services.

ESSENTIAL SERVICES.

He had taken pains to get an estimate of all the chemes of development in matters of public health efore the Ministry at the time of the oncoming of he effort for economy. These amounted roughly o £1,000,000 worth, and of that not more than 150,000 worth had to be abandoned as not essential. f the essential services he would put in the forefront t the present time the service of maternity and child elfare, and the service for dealing with the great courge of tuberculosis. They had now an important ew weapon in the fight against tuberculosis. Since he initiation of the new system of local administration, wing to the coordination of public assistance with ublic health services, they could now follow up cases hen they left the sanatorium. At the end of December, 1930, the number of beds available for he treatment of tuberculosis was 15,972 ; at the end f December, 1931, the number available was 17,609. There was no evidence there of relaxation of effort. At the end of 1931 the number of infant welfare centres n England and Wales was 3043, compared with 2935 at the end of 1930. The number of antenatal clinics n England and Wales at the end of 1931 was 1262, compared with 1101 at the end of 1930. As regards maternal mortality he knew that there was a scheme put forward under the late Labour Government for the service to which Mr. Lansbury had referred. but that scheme was typical of the complete lack of touch with realities in administration shown by the late Labour Government. It would have placed a burden on the country's finances of a nature which the country was totally unable to bear at the time. Nor was it well conceived to get the best possible use out of the public money required to finance it. But because that was a frank impossibility at this time did it mean that they were going to relax in the war on maternal mortality ? On the contrary, if they got rid of illusions they would be able to proceed in the most practical way to get the best use of the resources available. The Ministry had already sent a Circular to the local authorities for this purpose. There were services for promoting the welfare of mother and child before, at, and after birth, which local authorities could render, but they did not all render it. The Ministry was endeavouring to stimulate the local authorities to come up to the standard of the best, and make use of the powers which they already had. Further effort would be made to persuade those authorities which needed persuasion to strengthen their maternity services. Stress must be laid on the importance of educating the women themselves to take advantage of the services. Particular attention must be paid, of course, in the interests of economy to those areas in which the mortality among mothers was the highest.

PROGRESS OF COÖRDINATION.

The coördination of public health and public assistance was already yielding most valuable, interesting, and important results both in efficiency and economy. In the general scheme of the nation's finances there was no need for an immediate grip of parsimony in the public health services such as there was in some other national services, because there was a margin in the block grant for the development of the health services. When he spoke of the extension of the maternity services and the effort to secure a better standard among local authorities, he was relying upon the margin which was provided by the £5,000,000 increase in Exchequer money which was made available for local authorities at the time of the institution of the block grant system. That was one benefit from the new scheme. Another great benefit was the ability of the Ministry of Health to concentrate on its proper work as a clearing house of knowledge and information, and the source from which counsel and advice could proceed to keep the local authorities in touch with the best knowledge available for their service. The Ministry also had to be the staff brains of the whole national health services. Special inquiries had been carried out quite recently in the discharge of those staff functions into tuberculosis, cancer, and cerebro-spinal meningitis. Another bit of staff work which had been done at the Ministry of Health was in connexion with the important matter of nutrition. That was a modern science on which floods of fresh light were being cast every day, and it was difficult, even for the medical officers, to keep up to date with the latest information. In order to help them they had instituted a new standing advisory committee to collect the latest information on nutrition for the benefit of the medical profession and the public as a whole. The practical lesson of experience was that this was not very important for the middle and upper classes, which had a varied diet, but it was very important for the wage-earning classes, where diet was not so varied. The committee had brought out two reports, one on diet in poor-law children's homes, and the other on the vitamins, where the uninitiated could follow the natural history of these difficult subjects from vitamin A down to vitamin D, and even to vitamin E, and its function in promoting the fertility of rabbits.

HOSPITAL TRANSFER A SLOW PROCESS.

The classification of institutions, and in particular the transfer of hospitals from poor-law conditions to the new status of the general purposes hospital, was a problem which could not possibly be dealt with effectively in a short time. But he could say that the progress had been good and satisfactory, particularly in London. Sixty-eight institutions had been appropriated for special purposes following on a scheme of classification according to the last report. Since that report 11 more had been classified. There was nothing to complain of in the rate of progress there. The transfer from poor-law status to general public status in the case of hospitals was acting as a remarkable stimulus upon the institutions, since it made them, as it were, equals of the greatest and most famous hospitals in the land. It was the policy of the Ministry of Health to promote coöperation between voluntary and public hospitals in every possible way. The necessity of the voluntary hospitals as a part of our national scheme was recognised as an essential part of the structure. Both the voluntary hospitals and the public hospitals had their own useful fields of activity. He knew of no sense of hostility or antagonism between them, and there was no reason why there should be. The only rivalry was as to which could treat their patients best. The Ministry of Health must see that the

obviously not due to this Government, though it might be due in some part, if they could measure it, to the Local Government Act. The birth-rate in 1931 fell from 16·5 to 15·8, which was the lowest point yet attained, and the death-rate went up from 11·5 to 12·3, and infant mortality rose from 60 per 1000 to 66 per 1000. Fears had been expressed as to the future of our poor-law institutions, and they might have expected to see some decline in their efficiency as the result of the enormous task of transferring them to new authorities. He felt confident, however, that those fears had not been realised. Those who had worked professionally with the local authorities, or who were otherwise in close touch with their work, recognised that great advantages were accruing on the professional side of the work of those institutions.

ANOMALIES IN SMALL-POX ADMINISTRATION.

Take the appalling waste which arose from having *isolation hospitals all over a county*. He hoped the reorganisation under the Act would be carried on, because it would be of enormous advantage if they could bring it into effect in the next two or three years. As an extreme case let them take the provisions of small-pox hospitals. They all knew how inadequate had been the arrangements for dealing with a small-pox epidemic. It was quite clear that in the revision of the machinery for maintaining public health they must revise the vaccination laws and the whole of the vaccination machinery. To what extent was the transfer of powers under the Local Government Act preparing for such a division of the vaccination laws and their administration? He hoped that the county councils in taking over powers to deal with small-pox, sanitation, and vaccination would prepare sound schemes which would enable them to deal with the appalling anomaly which existed at the present time—this hypocrisy under which the country was supposed to have a system of compulsory vaccination when only one-third or one-fourth or less of the population now growing up were vaccinated.

VOLUNTARY HOSPITAL SYSTEM.

Another point they had to consider in developments under the Local Government Act was the threat to voluntary institutions—voluntary hospitals and voluntary agencies engaged in health work. The more they coördinated municipal work, and regularised the official system, the more difficult it was to fit in the voluntary system with it, and yet they all appreciated the enormous advantages of the voluntary system, where it was properly supported, in connexion with hospital work. Even the most extreme Socialist recognised that for the present the voluntary system must remain. It would be perfect madness to contemplate, even in the more distant future, any interference with the efficiency of voluntary hospitals and other institutions. They were constantly met by the statement that the work of raising money for voluntary hospitals and other institutions was degrading, and that they ought to be put on the rates. The advantage of the voluntary system was that those who gave to them generally helped to see that results were obtained from their contributions. Municipal hospitals generally had a much duller and less appetising air about them. The voluntary system was essential both to economy and efficiency. In London they saw the problem in its most acute form, though it was reflected all over the country. In London everything had been done by the officials to try and work in with the voluntary hospitals, and yet the voluntary hospitals felt that by degrees they were fighting a losing battle, and that it was more and more difficult for them to hold their own against the municipal side of hospital work. Perhaps the Minister of Health could reassure the House on that point.

LONDON MEDICAL SCHOOLS.

He had been in close touch with the 13 teaching voluntary hospitals in London, and they had been seriously perturbed by one fact. In the Local Government Act provision was made for a London Voluntary Hospitals Committee to be in constant consultation with the London County Council, but there were 150 hospitals represented on the committee, and the 13 teaching hospitals felt that they had not had their interests adequately considered. There was an idea that the London County Council were going to set up a central teaching hospital which would compete with the voluntary teaching hospitals which had been the foundation of British medicine. He did not believe that that was intended by the London County Council, but they were intending to carry out the splendid scheme introduced by the last Government but one for a post-graduate teaching centre in London. As regarded ordinary teaching, there was a definite part to be played by the voluntary hospitals and a definite part to be played by the poor-law hospitals. How should those two be brought together? There must be some clear understanding of their relative functions. *On the one hand* there were the voluntary hospitals, which must do the main work of teaching and research, which he did not think could be properly carried out by municipal institutions. The municipal hospitals ought to be working in coöperation with the voluntary teaching hospitals with a view to effecting greater economy. The municipal hospitals had a large range of clinical quarters in their medical schools which should be of great advantage to the rising medical profession and the nursing profession. The ordinary voluntary hospitals took one-fifth of the cases in London, and they would willingly help the poor-law infirmaries if arrangements could be made to do this. That would be an advantage to the hospitals and to the municipal institutions. It would also lead to a great economy, and help coöperation between municipal and voluntary hospitals which they all desired to see. There was a great future for coöperation between the laboratory services. They had been looking forward to the first revision of grants under the Local Government Act. Grants were made for three years as from April 10th, 1930, to 1933, and then the new bodies would *start to receive* grants for four years and afterwards for five years. He hoped it would not be necessary to reduce the grants, and that the power given in Section 104 of the Local Government Act would be found useful in bringing local authorities up to the mark.

After further debate,

The Opposition View.

Mr. LANSBURY said that at a period like the present it seemed to be absurd to say that they ought to economise on any public health service. In spite *of national need and money stringency* he maintained that a period of great unemployment was exactly the time when there ought to be more money spent on public health services. The London County Council and other local authorities had carried economy in health services much too far. He felt certain that when they received the next year's reports of the medical officers of the Ministry of Health, the Board of Education, and the London County Council they would show a very marked difference in the physique of the children. Mr Greenwood, when he was Minister of Health in the late Government, intended to introduce a Bill to deal with the problem of maternal mortality, but he was told that he could not bring it forward because of financial stringency. Was there any possibility of that particular Bill being passed this year? Every voluntary hospital in London was more or less in a bad way, and they were living from hand to mouth. On the education side some of their work was magnificently done. In regard to the poor-law hospital they were doing a fine work without any sort of stigma of pauperism about it at all. They were trying to create, although it did not exist yet, a real municipal health and *hospital service*. He wished to see a national medical service throughout the country, but meanwhile he would like to see, especially in ondon, real coöperation and coördination in the ork of municipal and voluntary hospitals.

Government Reply.

Sir E. HILTON YOUNG (Minister of Health), replying the debate, said that there had been a resolute tempt to represent that unwise restrictions were ing placed on the public health services in the terests of economy. For that suggestion there was o shadow of foundation of any sort or kind. The st argument used in favour of that contention was misquotation of a Circular on economy issued at he time of the national crisis to local authorities. he words of the Circular were:—

> "His Majesty's Government would not contemplate at local authorities should embark on a wholesale and l-considered course of cutting down expenditure, whatever e its character or purpose. Such a policy seems to them either necessary nor advisable."

Was there in that any reckless disregard of the fficiency of the services in the interests of economy? Further down in the Circular they found the special eservation that consideration was to be given as to whether a service was required on urgent grounds of public health. It was the policy of this Government, s it must be the policy of every Government which had the welfare of the country at heart, to consider public health as a matter of urgent national importance and to regard economy as false which would reduce he efficiency of the essential services.

ESSENTIAL SERVICES.

He had taken pains to get an estimate of all the schemes of development in matters of public health before the Ministry at the time of the oncoming of the effort for economy. These amounted roughly to £1.000.000 worth, and of that not more than £150.000 worth had to be abandoned as not essential. Of the essential services he would put in the forefront at the present time the service of maternity and child welfare, and the service for dealing with the great scourge of tuberculosis. They had now an important new weapon in the fight against tuberculosis. Since the initiation of the new system of local administration, owing to the coördination of public assistance with public health services, they could now follow up cases when they left the sanatorium. At the end of December, 1930, the number of beds available for the treatment of tuberculosis was 15.972: at the end of December, 1931, the number available was 17.609. There was no evidence there of relaxation of effort. At the end of 1931 the number of infant welfare centres in England and Wales was 3043, compared with 2935 at the end of 1930. The number of antenatal clinics in England and Wales at the end of 1931 was 1262, compared with 1101 at the end of 1930. As regards maternal mortality he knew that there was a scheme put forward under the late Labour Government for the service to which Mr. Lansbury had referred, but that scheme was typical of the complete lack of touch with realities in administration shown by the late Labour Government. It would have placed a burden on the country's finances of a nature which the country was totally unable to bear at the time. Nor was it well conceived to get the best possible use out of the public money required to finance it. But because that was a frank impossibility at this time did it mean that they were going to relax in the war on maternal mortality? On the contrary, if they got rid of illusions they would be able to proceed in the most practical way to get the best use of the resources available. The Ministry had already sent a Circular to the local authorities for this purpose. There were services for promoting the welfare of mother and child before, at, and after birth, which local authorities could render, but they did not all render it. The Ministry was endeavouring to stimulate the local authorities to come up to the standard of the best, and make use of the powers which they already had. Further effort would be made to persuade those authorities which needed persuasion to strengthen their maternity services. Stress must be laid on the importance of educating the women themselves to take advantage of the services. Particular attention must be paid, of course, in the interests of economy to those areas in which the mortality among mothers was the highest.

PROGRESS OF COÖRDINATION.

The coördination of public health and public assistance was already yielding most valuable, interesting, and important results both in efficiency and economy. In the general scheme of the nation's finances there was no need for an immediate grip of parsimony in the public health services such as there was in some other national services, because there was a margin in the block grant for the development of the health services. When he spoke of the extension of the maternity services and the effort to secure a better standard among local authorities, he was relying upon the margin which was provided by the £5.000.000 increase in Exchequer money which was made available for local authorities at the time of the institution of the block grant system. That was one benefit from the new scheme. Another great benefit was the ability of the Ministry of Health to concentrate on its proper work as a clearing house of knowledge and information, and the source from which counsel and advice could proceed to keep the local authorities in touch with the best knowledge available for their service. The Ministry also had to be the staff brains of the whole national health services. Special inquiries had been carried out quite recently in the discharge of those staff functions into tuberculosis, cancer, and cerebro-spinal meningitis. Another bit of staff work which had been done at the Ministry of Health was in connexion with the important matter of nutrition. That was a modern science on which floods of fresh light were being cast every day, and it was difficult, even for the medical officers, to keep up to date with the latest information. In order to help them they had instituted a new standing advisory committee to collect the latest information on nutrition for the benefit of the medical profession and the public as a whole. The practical lesson of experience was that this was not very important for the middle and upper classes, which had a varied diet, but it was very important for the wage-earning classes, where diet was not so varied. The committee had brought out two reports, one on diet in poor-law children's homes, and the other on the vitamins, where the uninitiated could follow the natural history of these difficult subjects from vitamin A down to vitamin D, and even to vitamin E, and its function in promoting the fertility of rabbits.

HOSPITAL TRANSFER A SLOW PROCESS.

The classification of institutions, and in particular the transfer of hospitals from poor-law conditions to the new status of the general purposes hospital, was a problem which could not possibly be dealt with effectively in a short time. But he could say that the progress had been good and satisfactory, particularly in London. Sixty-eight institutions had been appropriated for special purposes following on a scheme of classification according to the last report. Since that report 11 more had been classified. There was nothing to complain of in the rate of progress there. The transfer from poor-law status to general public status in the case of hospitals was acting as a remarkable stimulus upon the institutions, since it made them, as it were, equals of the greatest and most famous hospitals in the land. It was the policy of the Ministry of Health to promote coöperation between voluntary and public hospitals in every possible way. The necessity of the voluntary hospitals as a part of our national scheme was recognised as an essential part of the structure. Both the voluntary hospitals and the public hospitals had their own useful fields of activity. He knew of no sense of hostility or antagonism between them, and there was no reason why there should be. The only rivalry was as to which could treat their patients best. The Ministry of Health must see that the

obviously not due to this Government, though it might be due in some part, if they could measure it, to the Local Government Act. The birth-rate in 1931 fell from 16·5 to 15·8, which was the lowest point yet attained, and the death-rate went up from 11·5 to 12·3, and infant mortality rose from 60 per 1000 to 66 per 1000. Fears had been expressed as to the future of our poor-law institutions, and they might have expected to see some decline in their efficiency as the result of the enormous task of transferring them to new authorities. He felt confident, however, that those fears had not been realised. Those who had worked professionally with the local authorities, or who were otherwise in close touch with their work, recognised that great advantages were accruing on the professional side of the work of those institutions.

ANOMALIES IN SMALL-POX ADMINISTRATION.

Take the appalling waste which arose from having isolation hospitals all over a county. He hoped the reorganisation under the Act would be carried on, because it would be of enormous advantage if they could bring it into effect in the next two or three years. As an extreme case let them take the provisions of small-pox hospitals. They all knew how inadequate had been the arrangements for dealing with a small-pox epidemic. It was quite clear that in the revision of the machinery for maintaining public health they must revise the vaccination laws and the whole of the vaccination machinery. To what extent was the transfer of powers under the Local Government Act preparing for such a division of the vaccination laws and their administration? He hoped that the county councils in taking over powers to deal with small-pox, sanitation, and vaccination would prepare sound schemes which would enable them to deal with the appalling anomaly which existed at the present time—this hypocrisy under which the country was supposed to have a system of compulsory vaccination when only one-third or one-fourth or less of the population now growing up were vaccinated.

VOLUNTARY HOSPITAL SYSTEM.

Another point they had to consider in developments under the Local Government Act was the threat to voluntary institutions—voluntary hospitals and voluntary agencies engaged in health work. The more they coördinated municipal work, and regularised the official system, the more difficult it was to fit in the voluntary system with it, and yet they all appreciated the enormous advantages of the voluntary system, where it was properly supported, in connexion with hospital work. Even the most extreme Socialist recognised that for the present the voluntary system must remain. It would be perfect madness to contemplate, even in the more distant future, any interference with the efficiency of voluntary hospitals and other institutions. They were constantly met by the statement that the work of raising money for voluntary hospitals and other institutions was degrading, and that they ought to be put on the rates. The advantage of the voluntary system was that those who gave to them generally helped to see that results were obtained from their contributions. Municipal hospitals generally had a much duller and less appetising air about them. The voluntary system was essential both to economy and efficiency. In London they saw the problem in its most acute form, though it was reflected all over the country. In London everything had been done by the officials to try and work in with the voluntary hospitals, and yet the voluntary hospitals felt that by degrees they were fighting a losing battle, and that it was more and more difficult for them to hold their own against the municipal side of hospital work. Perhaps the Minister of Health could reassure the House on that point.

LONDON MEDICAL SCHOOLS.

He had been in close touch with the 13 teaching voluntary hospitals in London, and they had been seriously perturbed by one fact. In the Local Government Act provision was made for a London Voluntary Hospitals Committee to be in constant consultation with the London County Council, but there were 150 hospitals represented on the committee, and the 13 teaching hospitals felt that they had not had their interests adequately considered. There was an idea that the London County Council were going to set up a central teaching hospital which would compete with the voluntary teaching hospitals which had been the foundation of British medicine. He did not believe that that was intended by the London County Council, but they were intending to carry out the splendid scheme introduced by the last Government but one for a post-graduate teaching centre in London. As regarded ordinary teaching, there was a definite part to be played by the voluntary hospitals and a definite part to be played by the poor-law hospitals. How should those two be brought together? There must be some clear understanding of their relative functions. On the one hand there were the voluntary hospitals, which must do the main work of teaching and research, which he did not think could be properly carried out by municipal institutions. The municipal hospitals ought to be working in coöperation with the voluntary teaching hospitals with a view to effecting greater economy. The municipal hospitals had a large range of clinical quarters in their medical schools which should be of great advantage to the rising medical profession and the nursing profession. The ordinary voluntary hospitals took one-fifth of the cases in London, and they would willingly help the poor-law infirmaries if arrangements could be made to do this. That would be an advantage to the hospitals and to the municipal institutions. It would also lead to a great economy, and help coöperation between municipal and voluntary hospitals which they all desired to see. There was a great future for coöperation between the laboratory services. They had been looking forward to the first revision of grants under the Local Government Act. Grants were made for three years as from April 10th, 1930, to 1933, and then the new bodies would start to receive grants for four years, and afterwards for five years. He hoped it would not be necessary to reduce the grants, and that the *power given in Section 104 of the Local Government* Act would be found useful in bringing local authorities *up to the mark.*

After further debate,

The Opposition View.

Mr. LANSBURY said that at a period like the present it seemed to be absurd to say that they ought to economise on any public health service. In spite of national need and money stringency he maintained that a period of great unemployment was exactly the time when there ought to be more money sp on public health services. The London Count Council and other local authorities had carried economy in health services much too far. He felt certain that when they received the next year's reports of the medical officers of the Ministry Health, the Board of Education, and the Londo County Council they would show a very mar difference in the physique of the children. Greenwood, when he was Minister of Health in th late Government, intended to introduce a Bill to dea with the problem of maternal mortality, but he w told that he could not bring it forward because financial stringency. Was there any possibility o that particular Bill being passed this year? E voluntary hospital in London was more or less in bad way, and they were living from hand to m On the education side some of their work was ficently done. In regard to the poor-law hospital they were doing a fine work without any sort of of pauperism about it at all. They were trying t create, although it did not exist yet, a real municipa health and hospital service. He wished to see national medical service throughout the count but meanwhile he would like to see, especially ndon, real coöperation and coordination in the ork of municipal and voluntary hospitals.

Government Reply.

Sir E. HILTON YOUNG (Minister of Health), replying the debate, said that there had been a resolute tempt to represent that unwise restrictions were ing placed on the public health services in the terests of economy. For that suggestion there was shadow of foundation of any sort or kind. The st argument used in favour of that contention was misquotation of a Circular on economy issued at e time of the national crisis to local authorities. he words of the Circular were:—

> "His Majesty's Government would not contemplate at local authorities should embark on a wholesale and -considered course of cutting down expenditure, whatever its character or purpose. Such a policy seems to them ither necessary nor advisable."

Was there in that any reckless disregard of the ficiency of the services in the interests of economy? urther down in the Circular they found the special servation that consideration was to be given as to hether a service was required on urgent grounds of ublic health. It was the policy of this Government, s it must be the policy of every Government which ad the welfare of the country at heart, to consider ublic health as a matter of urgent national importance nd to regard economy as false which would reduce he efficiency of the essential services.

ESSENTIAL SERVICES.

He had taken pains to get an estimate of all the chemes of development in matters of public health efore the Ministry at the time of the oncoming of he effort for economy. These amounted roughly o £1.000,000 worth, and of that not more than 150,000 worth had to be abandoned as not essential. Of the essential services he would put in the forefront t the present time the service of maternity and child welfare, and the service for dealing with the great scourge of tuberculosis. They had now an important new weapon in the fight against tuberculosis. Since the initiation of the new system of local administration, owing to the coordination of public assistance with public health services, they could now follow up cases when they left the sanatorium. At the end of December, 1930, the number of beds available for the treatment of tuberculosis was 15,972; at the end of December, 1931, the number available was 17,609. There was no evidence there of relaxation of effort. At the end of 1931 the number of infant welfare centres in England and Wales was 3043, compared with 2935 at the end of 1930. The number of antenatal clinics in England and Wales at the end of 1931 was 1262. compared with 1101 at the end of 1930. As regards maternal mortality he knew that there was a scheme put forward under the late Labour Government for the service to which Mr. Lansbury had referred, but that scheme was typical of the complete lack of touch with realities in administration shown by the late Labour Government. It would have placed a burden on the country's finances of a nature which the country was totally unable to bear at the time. Nor was it well conceived to get the best possible use out of the public money required to finance it. But because that was a frank impossibility at this time did it mean that they were going to relax in the war on maternal mortality? On the contrary, if they got rid of illusions they would be able to proceed in the most practical way to get the best use of the resources available. The Ministry had already sent a Circular to the local authorities for this purpose. There were services for promoting the welfare of mother and child before, at, and after birth, which local authorities could render, but they did not all render it. The Ministry was endeavouring to stimulate the local authorities to come up to the standard of the best, and make use of the powers which they already had. Further effort would be made to persuade those authorities which needed persuasion to strengthen their maternity services. Stress must be laid on the importance of educating the women themselves to take advantage of the services. Particular attention must be paid, of course, in the interests of economy to those areas in which the mortality among mothers was the highest.

PROGRESS OF COÖRDINATION.

The coördination of public health and public assistance was already yielding most valuable, interesting, and important results both in efficiency and economy. In the general scheme of the nation's finances there was no need for an immediate grip of parsimony in the public health services such as there was in some other national services, because there was a margin in the block grant for the development of the health services. When he spoke of the extension of the maternity services and the effort to secure a better standard among local authorities, he was relying upon the margin which was provided by the £5,000,000 increase in Exchequer money which was made available for local authorities at the time of the institution of the block grant system. That was one benefit from the new scheme. Another great benefit was the ability of the Ministry of Health to concentrate on its proper work as a clearing house of knowledge and information, and the source from which counsel and advice could proceed to keep the local authorities in touch with the best knowledge available for their service. The Ministry also had to be the staff brains of the whole national health services. Special inquiries had been carried out quite recently in the discharge of those staff functions into tuberculosis, cancer, and cerebro-spinal meningitis. Another bit of staff work which had been done at the Ministry of Health was in connexion with the important matter of nutrition. That was a modern science on which floods of fresh light were being cast every day, and it was difficult, even for the medical officers, to keep up to date with the latest information. In order to help them they had instituted a new standing advisory committee to collect the latest information on nutrition for the benefit of the medical profession and the public as a whole. The practical lesson of experience was that this was not very important for the middle and upper classes, which had a varied diet, but it was very important for the wage-earning classes, where diet was not so varied. The committee had brought out two reports, one on diet in poor-law children's homes, and the other on the vitamins, where the uninitiated could follow the natural history of these difficult subjects from vitamin A down to vitamin D, and even to vitamin E, and its function in promoting the fertility of rabbits.

HOSPITAL TRANSFER A SLOW PROCESS.

The classification of institutions, and in particular the transfer of hospitals from poor-law conditions to the new status of the general purposes hospital, was a problem which could not possibly be dealt with effectively in a short time. But he could say that the progress had been good and satisfactory, particularly in London. Sixty-eight institutions had been appropriated for special purposes following on a scheme of classification according to the last report. Since that report 11 more had been classified. There was nothing to complain of in the rate of progress there. The transfer from poor-law status to general public status in the case of hospitals was acting as a remarkable stimulus upon the institutions, since it made them, as it were, equals of the greatest and most famous hospitals in the land. It was the policy of the Ministry of Health to promote coöperation between voluntary and public hospitals in every possible way. The necessity of the voluntary hospitals as a part of our national scheme was recognised as an essential part of the structure. Both the voluntary hospitals and the public hospitals had their own useful fields of activity. He knew of no sense of hostility or antagonism between them, and there was no reason why there should be. The only rivalry was as to which could treat their patients best. The Ministry of Health must see that the

two divisions in the hospital structure should each pay due regard to the opportunities and possibilities of the other, and that each should be duly fitted into the structure. The review of boundaries was proceeding as fast as the difficulties would allow. They had to reconcile old traditions, old prejudices, and, in some cases, old antipathies, in order to carry out arrangements desirable in the interests of economy and efficiency in the modern world. On the whole progress had been satisfactory. Nine reviews had been completed, and four more inquiries had been held, which would lead to a decision very shortly. In addition to those 13, 15 others were being arranged, and as regards some others it was necessary to give those extensions of time which the Act contemplated. It was the policy of the Ministry of Health to encourage the making of exclusive declarations where it was possible in order to complete the process of segregation of activity which was the primary object of the Local Government Act. Here, again, a careful survey of all the services necessary was made, and in many cases a survey of the institutions must proceed to a fairly complete stage before a declaration could be made. Therefore they could not expect many declarations just yet. The number made last year was five, in addition to those already mentioned.

POST-GRADUATE SCHOOL.

As to the situation in regard to the post-graduate school, that was a typical instance of how the voluntary hospitals and the public hospitals could discharge complementary functions in the whole scheme of hospital accommodation. The post-graduate school had now come to birth, and they believed that it would be of very great promise for the future of medical science, medical education, and the health of the people. It had come to birth at the London County Council hospital at Hammersmith. It would be a school in connexion with a public general hospital, the only one of the kind. The present stage of its evolution was this: the Charter had been granted and the governing body set up. At present the actual organisation of the school and a scheme for the provision of buildings for the school were being worked out, and before very long they hoped to see this school an established fact.

Replying to Mr. D. GRENFELL, Mr. ERNEST BROWN (Parliamentary Secretary to the Ministry of Health) said that if the hon. Member would study the last Report, that for 1930, issued by the chief medical officer of the Ministry, he would find a most valuable section dealing with cancer, and another section dealing with rheumatic diseases. So far from being lax in this matter the Ministry was thoroughly alive to the need for research, as well as for action in connexion with those diseases.

Dr. MORRIS-JONES asked leave to withdraw his motion.

The motion was withdrawn.

HOUSING POLICY.

Replying to a debate on housing policy which followed,

Sir E. HILTON YOUNG said that each house approved for subsidy would incur to the Exchequer a liability of £130, and a consequential liability to the local authority of £65, so that the liability to public funds incurred by each house approved for subsidy was £190—the equivalent of a charge on the Exchequer of £7 10s. per year for 40 years. That showed how serious was still the liability, even with the fall in the cost of housing, involved in the approval of houses for subsidy. He warned the House that in the present state of national finance it was not possible to look upon that obligation lightly. Already the annual recurring liability in the national budget for housing was £12,750,000. Since the war the number of houses built had been 1,820,000. The increase in population between 1921 and 1931 was 2,000,000. The result was that at the present time over the country as a whole the average number of persons to a house was barely four. That did not show that there was no longer a housing problem, because there was not an even distribution over every class of house and all over the country. It showed, if they took the country as a whole, that there was no evidence of a housing shortage. It meant that in each proposition for fresh housing they must consider whether the area in question was one of the areas that was in need of more housing accommodation. It was established that there was no longer any need for a great State effort to provide the kind of housing which for the most part they had been providing, and that they had provided enough of the better class subsidised house. What they had not done was to provide enough smaller houses for the poor person. They must, therefore, concentrate the whole housing effort on the provision of smaller houses for the wage-earners which required State assistance. That was the policy of the Government at the present time.

With regard to the slum areas, Sir E. Hilton Young said that the remedying of that evil must always continue along with the adequate supply of new houses of the type which the country required Under the Act of 1930 a very drastic method was applied for dealing with the problem. That Act was a very powerful engine, and needed to be used with great caution. He was not surprised, therefore, that the local authorities were proceeding slowly in that matter. Nevertheless, under that Act schemes had been passed for clearance areas which would finally lead to the clearing away of 13,500 unfit slum houses. So far the number of houses dealt with under the Housing (Rural Workers) Act, 1926, was 4469, and he hoped that further use would be made of that Act. The applications received for the construction of houses under the Housing (Rural Authorities) Act, 1931, had not been so large as was expected, but 112 applications had been received for some 2000 houses, which were now under construction. Rebutting the suggestion that the Government were relaxing in a substantial degree their housing effort owing to the influences of considerations of economy, Sir E. Hilton Young said that at the end of February there were 38,450 assisted houses under construction, and on the corresponding day in February in the year before there were 36,000. This showed that there was no falling off in the building effort of the country.

The motion that the Speaker do leave the Chair was agreed to.

TRANSITIONAL PAYMENTS BILL.

The Transitional Payments Prolongation (Unemployed Persons) Bill was read the third time.

This Bill was read the third time in the House of Lords on Thursday, April 14th, and afterwards received the Royal Assent.

REGISTRATION OF FOOD FACTORIES.

On Tuesday, April 12th, the London County Council (General Powers) Bill was considered by a Select Committee of the House of Commons.

The Hon. EVAN CHARTERIS, K.C. (who appeared for the L.C.C.), said that the part of the Bill which was opposed was Clause 16. The purpose of that clause was to enable the Council to compel the registration of certain premises in which certain kinds of food were prepared or manufactured. The clause required the registration of—

> "any premises in the district of any sanitary authority used or proposed to be used (1) for the sale, or the manufacture for the purpose of sale, of ice-cream or other similar commodity, or the storage of ice-cream or other similar commodity intended for sale; or (2) for the preparation or manufacture of sausages, or potted, pressed, pickled, or preserved meat, fish, or other food intended for sale."

The object of the Council, Mr. Charteris said, was to anticipate the evil, instead of punishing those found guilty of it, by registering the premises in which these various processes were carried on. The proposals in regard to ice-cream were not opposed, but there s a petition against the other portion by the tional Federation of Meat Traders' Associations.

Dr. **Charles Porter**, called as a witness on behalf the promoters, said that the principal factor which dered this such an important matter was that less there was adequate control of food there was ious risk of contamination, with consequent injury public health. The Society of Medical Officers of alth, he said, had always been in favour of registra- n, without which it was quite impossible to know e situation of the places where this work was carried , and to take measures to avoid the risk of con- mination. There was a great increase at the esent time in the use of cooked foods and foods hich could be easily cooked. Sausages were one the most commonly used articles of food among orer people, and food-poisoning cases were almost variably due to foods of this type.

The Committee decided to allow Clause 16 to remain the *Bill*.

THE BUDGET.

On Tuesday, April 19th, the House of Commons ent into Committee of Ways and Means, Sir D. **Herbert** in the chair.

Mr. **Chamberlain**, Chancellor of the Exchequer, *the course of his Budget statement, said that in* eptember last, at the time of the national crisis, here was a prospective deficit of £74.000,000. To ake good that deficiency and to balance the national ccounts demanded the highest courage and deter- mination on the part of the Chancellor of the Exchequer, and supreme confidence in the readiness f the people to undertake whatever burdens and acrifices might be laid upon them in order to support he national credit. (Cheers.) By a combination of economy and new taxation Mr. (now Lord) Snowden had provided for a reduction of debt by £32.500,000, and for a surplus of £1.500,000. Not only had his noble friend's anticipations been fulfilled but, together with the small surplus of £364,000 which had actually been achieved, must be taken the fact that, instead of £23,000.000 being appropriated from the Dollar Exchange Fund, as was proposed in September, it had only been necessary to take £12,750,000. They were therefore £9,000,000 better off than Lord Snowden had anticipated. (Cheers.) That result had produced a profound impression upon instructed opinion in all parts of the world. (Cheers.) In spite of the concessions which the Government had made on the pay cuts originally proposed the estimated economies had been more than met, and, the reduction of unemployment coming to their aid, they were able in the end to show savings amounting altogether to £34,500,000, compared with Lord Snowden's proposed economies of £22,000,000.

Proceeding to deal with the estimates for this year, Mr. Chamberlain said that nothing was included in respect of receipts for reparations and allied war debts, or in respect of outgoings for war debt payments. Both sides of the account were treated as being in suspense. Similarly, nothing was included in respect of receipts for those Dominion war debts, the service of which had been suspended until July 1st next. This meant a shortage of £10,000,000 as compared with the forecast of last September, which assumed that after the expiration of the Hoover Moratorium the previous position of reparations and war debts would be restored. Last September the total for supply services for 1932–33 was estimated at £526,000,000. It was proposed to effect economies of £70,000,000, leaving the total at £456,000,000. Actually the estimates *presented to* Parliament showed a total of only £447.204.000. The savings therefore amounted to nearly £79,000,000 in spite of concessions in pay cuts costing £3,500,000, and of unprovided expenditure to the amount of about £1,250,000 for income tax collection and work under the Import Duties Act. It was estimated that there would be a decrease of £10,000,000 in surtax, and £28,000,000 in income tax compared with the estimates for last year. The total inland revenue was estimated at £427,000,000, or more than £32,500,000 less than the figure provisionally put forward in September. Customs and excise were estimated to yield £297,500,000, or about £40,000,000 more than last year. He regretted that there was no opportunity this year of giving any relief to the income-tax payer. Nor could he make any change in the beer duty. The rates of duty on motor-cycles would be fixed at 15*s*., 30*s*., and £3, according as to whether the engine was of a capacity not exceeding 150 c.cm. and not exceeding 250 c.cm., and exceeding 250 c.cm. respectively. This scale would come into force on Jan. 1st, 1933. Any cycle registered for the first time before Jan. 1st next, on which duty had been paid at the rate applicable to a cycle under 224 lb. unladen weight, would in future continue to be liable to the lower rate of duty applicable to cycles with an engine capacity between 150 and 250 c.cm. The tea duty would be raised to 4*d*. per lb. on foreign tea, with a preference of 2*d*. per lb. in favour of Empire tea. The final balance sheet showed an estimated expenditure of £766,004,000 and an estimated revenue (including £33,000,000 from the 10 per cent. revenue tariff, horticultural products duty, additional duties recommended by the advisory committee, and the proposed changes in *taxation) of £766,800,000. This left an estimated* surplus of £796,000.

HOUSE OF COMMONS.

TUESDAY, APRIL 12TH.

Health and Housing in Scotland.

Mr. **Barclay-Harvey** asked the Secretary for Scotland the total amounts expended on health and housing, exclusive of relief to unemployed persons, by the Government and local authorities in Scotland in the financial years 1912–13 and 1930–31, respectively.—Mr. **Skelton** replied: I regret that information for the year 1930–31 is not yet available. The following table gives the expenditure on housing and health services in Scotland during the years ended May 15th, 1913, and 1930.

Service.		Expenditure out of— Parliamentary votes and grants.	Local rates.	Other receipts (rents, &c.)	Total expenditure.
		£	£	£	£
Housing ..	1913	Nil.	38,310	105,872	114,182
	1930	1,621,000	656,000	2,442,000	4,719,000
Health Services *	1913	30,000†	390,358	10,000‡	430,358
	1930	625,000	1,006,000	41,000	1,672,000

* Comprises hospitals, treatment of disease (including tuberculosis and venereal diseases) and maternity and child welfare

† Estimated proportion of grants for general expenditure.

‡ Estimated.

WEDNESDAY, APRIL 13TH.

Hospitals and Motor Accidents.

Sir **John Haslam** asked the Minister of Transport if he was aware that, according to the British Medical Association, 7326 motor accidents were treated in 135 hospitals during 1931, incurring a total cost to the hospitals of £64,132, and that the claims repaid under the Road Traffic Act amounted to £6575 or about 10 per cent.; and what steps he proposed to take in order that the expectations under the Act could be realised.—Mr. **Pybus** replied: As I stated on Feb. 17th, in answer to a somewhat similar question, while I sympathise with the difficulties of the hospitals I am afraid I cannot see my way to introduce further legislation.

Motor Accidents: Responsibility and Compensation.

Mr. **Rhys Davies** asked the Home Secretary the number of motor accidents in which the police had failed to trace some of the responsible parties during the last six years, and the number of cases in which compensation in some form or other had been paid to the victims of those accidents.—Mr. **Stanley** (Under Secretary, Home Office) replied: I am informed by the Commissioner of Police that during the last six years there have been eight persons killed in the metropolitan police district by unknown vehicles. Corresponding figures for the rest of the country are *not available*, nor as to non-fatal accidents in the metropolitan police district. No information is available as to the number of such cases in which compensation has been paid.

Supply of Medicines in Rural Districts.

Mr. PERKINS asked the Minister of Health whether his attention had been called to the fact that insured persons living in the village of Edgeworth, Gloucestershire, had to walk six miles to Painswick to obtain medicine; and whether he would consider the advisability of the establishment of a surgery in the village of Miserden.—Sir E. HILTON YOUNG replied: My attention has not previously been drawn to this matter, but I am making inquiry and will communicate further with my hon. friend.

THURSDAY, APRIL 14TH.

Cost of Health and Housing Schemes.

Mr. BARCLAY-HARVEY asked the Minister of Health what was the total cost of health and housing schemes of the Government and local authorities in England and Wales in the financial years 1912–13 and 1930–31 respectively, excluding any sums paid in relief of unemployment.—Sir E. HILTON YOUNG replied: It is assumed that the health schemes of local authorities referred to by my hon. friend are those which, prior to April 1st, 1930, were assisted by direct Government grants. These grants (except the Port Sanitary grant) were discontinued by the Local Government Act, 1929, and were merged in the new Exchequer grants which are paid towards local government expenses generally, and cannot be apportioned to individual services. I am appending a statement relating to 1912–13 and 1929–30 (the latest year for which figures are available), showing the gross expenditure of local authorities on these services and on the housing service, the Government grants, and other specific income in aid of the services, and the balance of expenditure not met out of specific income. (See Table.)

Statement showing the Expenditure and Income of Local Authorities in England and Wales in Respect of the Undermentioned Services.

Service.	YEAR 1912–13. Total expenditure other than out of loans.	Income other than from loans.		Balance of expenditure not met out of specific income.	YEAR 1929–30. Total expenditure other than capital expenditure.	Income other than capital receipts.		Balance of expenditure not met out of specific income.
		Government grants.	Other specific income.			Government grants (*a*).	Other specific income.	
	£	£	£	£	£	£	£	£
Tuberculosis	95,500	30,000	35,500	30,000	3,338,940	1,697,849	117,467	1,523,624
Venereal diseases ..	—	—	—	—	411,341	300,313	1,266	109,762
Maternity and child welfare	—	—	—	—	2,408,801	936,246	446,319	1,020,236
Port sanitary	47,500	3,900	14,200	29,400	107,085	41,927	13,639	51,418
Welfare of the blind ..	—	—	—	—	468,795	8,470	31,474	428,851
Mental hospitals ..	4,288,000	998,000	580,000	2,710,000	9,052,325	1,119,689	1,847,144	6,085,492
Mental deficiency ..	—	—	—	—	1,500,244	678,250	127,604	694,390
Housing:—								
Assisted housing schemes under Housing, &c., Act, 1919	—	—	—	—	14,094,401	6,744,135	6,160,700	1,149,566
Other State-aided housing schemes ..	—	—	—	—	16,714,816	4,595,073	10,939,865	1,161,878
Other housing schemes	850,000	—	647,000	304,000	1,625,584	1,606	1,366,829	257,147

(*a*) Including grants made in connexion with schemes of work for the unemployed. The amounts of these grants are not distinguished from other grants.

Examination of Girls Concerned in Sexual Offences.

Captain ELLISTON asked the Home Secretary whether arrangements were being made to appoint women medical officers for the examination of girls concerned in sexual offences, in accordance with the requests of moral welfare committees in the metropolitan area.—Sir HERBERT SAMUEL replied: The number of cases is not great enough to warrant special appointments, whether of men or of women, for this purpose. If in any particular case the parents of the child desired that the examination should be conducted by a woman doctor and one were available, her services would be utilised.

Sweepstakes.

Mr. HUTCHISON asked the Home Secretary whether there would be any alteration in the administration of the law affecting sweepstakes by his department during the period in which that question was being examined by the proposed Royal Commission.—Sir HERBERT SAMUEL replied: I do not contemplate any alteration.

Slum Clearance Schemes.

Mr. GROVES asked the Minister of Health how many slum clearance schemes were at present being carried out in England and Wales; the total number of houses to be demolished; and the total number of houses to be constructed.—Sir E. HILTON YOUNG replied: I have received resolutions declaring 417 areas in England and Wales, the clearance of which involves the demolition of approximately 14,000 houses, to be clearance areas under the Housing Act 1930. It is anticipated that houses sufficient for the accommodation of 68,000 persons will be provided.

Town and Country Planning Bill.

Mr. LOGAN asked the Minister of Health what action it was proposed to take to ensure the passing of the Town and Country Planning Bill this session.—Sir E. HILTON YOUNG replied: I hope that no special action will be required to ensure the passing of the Bill this session.

Incurable Disease in Britain.

Mr. RHYS DAVIES asked the Minister of Health if he any information as to the number of persons sufferi from incurable disease in this country, and the number fo whom accommodation was provided by voluntary organis tions; and whether there were any public institutions incurables who were unable to look after themselves, apart from mental institutions.—Sir E. HILTON YOUNG replied: I regret that I am not in possession of any st on the points raised in the question. I do not know any institutions that exactly answer the description the last part of the question.

TUESDAY, APRIL 19TH.

Cerebral Fever at Windsor.

Mr. MCENTEE asked the Financial Secretary to the W Office how many of the cases of cerebral meningitis Windsor were among troops quartered in the barracks; how many were among troops in the old quarters; and whether full sanitary provisions were mad in the quarters of the guard at Windsor Castle—Mr. Du COOPER replied: There are no strictly modern barracks a Windsor, although improvements have been introduce from time to time. Since Jan. 1st there have been cases of cerebro-spinal fever, five of which occurred Victoria Barracks, and four at Combermere Ba The answer to the last part of the question is in affirmative.

OBITUARY

ARTHUR JERVIS, M.D. Durh., D.P.H. Camb.

HE recent death of Arthur Jervis, although it did come as a surprise to those who knew him best, ught to all his friends a sense of the loss of a able personality. He was little in the public , but he lived a life of great helpfulness to his le. He was educated at St. George's Hospital, l after taking the usual double qualification in 35, he matriculated at Durham and took the M.B. d B.S. of that University in 1889, the M.D. in 97, and the D.P.H. of Cambridge in 1895. He ved as house surgeon at the Dreadnought Hospital d he was house physician and assistant registrar St. George's. Soon after he qualified he had a ief experience of practice, but he disliked it and ve it up. When the war came in 1914 he volunteered r service, but, as was too often the case with similar fers, he was told that “ veterans were not wanted.” e was determined to be useful, however, and returned his old hospital as house physician and surgeon for year, serving under some of those who in earlier ys had been his clinical clerks. Even after this was not acceptable to the home authorities, it the French Red Cross gladly accepted his services d he spent many months in the Verdun area. His timate knowledge of the language enhanced the alue of his services and he had the unusual privilege being taken over the whole of the French front. fter these adventures the home authorities at length ave him a commission and utilised his services for ome months in the examination of recruits. He was hen transferred for service in hospital ships and he erved in these until the end of the war. Unfortunately n his last voyage to Palestine he contracted malaria hich developed after his return home. For the est of his life he had to submit to impaired health, nd he became too conscious of a degree of deafness ; his was not bad enough to interfere with the willing elp which he gave to others, but it made him shy f what he called “inflicting himself on his friends.” But no one who knew him could call a visit from Jervis an infliction, for he was full of interests and knowledge. An intimate circle of friends is left to deplore his death.

JOHN HENRY SALTER, M.R.C.S. Eng., D.L., J.P.

A REAL personality in the medical profession, Dr. John Henry Salter, of Tolleshurst D'Arcy has died at the great age of 91; having been 67 years in a country practice he died in harness, indeed it is only a few days since he was reappointed medical officer of health for his own district of rural Essex.

Dr. Salter whose whole life has been associated with Essex, received his medical education at King's College Hospital and took the qualifications of M.R.C.S. Eng., L.S.A. Lond., in 1864. He has himself recorded that his original intention was to devote himself to pure surgery, but he considered that the loss of an eye in a shooting accident would be a drawback to his prospects, and settled down to country practice as quite a young man. He met with great professional and social success. In the straggling district of Essex marked out by the towns of Colchester, Chelmsford, and Maldon, he was known personally or by repute to everyone—he may be said to have been an institution both as doctor and sanitarian. But his fame as a sportsman was perhaps greater and was certainly more widely spread than as a doctor. The loss of an eye did not prevent him from becoming famous as a shot and his home, D'Arcy House, was full of sporting trophies. He is reported to have kept a diary throughout his extensive life, and seeing the changes which that life has seen in the profession of which he was a devoted exponent, it is to be hoped that parts at least of his diary will be free for publication. The diary of the medical man must contain much unfitted for the public eye, but in a record of 60 or 70 years of country practice there must lie a picture of English society of great significance. And this the more that Dr. Salter knew, and, indeed, was the personal friend of many distinguished people outside the county of Essex, where he was a magistrate and deputy-lieutenant.

MEDICAL NEWS

University of Cambridge.

At recent examinations the following candidates were successful :—

D.M.R.E.

Part I.—G. I. Benjamin, C. C. Divanji, E. D. G. Gillies, John Lumb, A. B. Sullivan, and J. B. Watson.

Part II.—J. S. Brown, G. T. Calthrop, E. N. Cook, E. R. Crisp, Marjorie P. C. Greene, J. P. Grieve, H. J. Ham, J. P. Hederman, M. H. Hellman, J. N. Jacobson, J. L. Razdan, F. G. Stewart, and E. R. Williams.

University of London.

At recent examinations the following candidates were successful :—

D.P.H.

Part I.—C. A. Bozman, C. J. H. Brink, C. G. H. Campbell, E. J. de Verteuil, Mary G. H. Dickson, A. R. Forbes, Agnes B. Francklyn, T. O. Garland, J. C. P. Grey, T. C. John, F. B. Khambatta, George Macdonald, H. A. Mackenzie-Wintle, Dorothy Makepeace, R. B. Mayfield, R. M. Morris, A. R. Thompson, and K. C. Uppal.

National University of Ireland.

University College, Cork.—At recent examinations the following candidates were successful :—

THIRD EXAMINATION FOR M.B., B.CH.

Part I.—R. A. Coughlan, P. J. Geoghegan, D. C. Lawton, and D. G. O'Driscoll.

Part II.—James Fitzgerald and Thomas Sheahan.

D.P.H.

Mary C. O'Connell (second class honours) and Nora O'Connor.

University of Glasgow.

On April 16th, the following degrees were conferred :—

M.D.—P. J. Molloy and D. Russell (with commendation), J. W. Crawford, J. F. Hamilton, M. S. Purvis, B. Reid, and S. C. Shanks.

M.B.—A. C. Lendrum (with commendation), J. J. Barton, I. E. Bernstein, J. Bolton, W. Boyd, W. Brownlie, R. P. Butler, I. Camrass, S. A. Carloo, W. G. Cowan, Edith D. Dempster, W. M. Dennison, M. C. Dickson, M. C. G. Dods, Mary M. Downes, J. S. Gemmill, J. D. Gillies, Margaret R. Gilmour, Margaret M. Goudie, D. Houston, A. Kelly, G. A. Macdonald, T. C. Macdonald, Barbara A. A. McGeachy, J. McGovern, I. R. MacIntyre, I. MacKinnon, D. T. Maclay, E. McNamara, A. McD. Maiden, H. D. Miller, D. Murray, J. H. Neill, A. F. Rodger, L. D. W. Scott, W. B. Shaw, D. M. Walker, and R. J. Wotherspoon.

Scottish Conjoint Board.

As a result of recent examinations of the conjoint examining board of the Royal Colleges of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow, the following candidates have been granted the diplomas of L.R.C.P. Edin., L.R.C.S. Edin., L.R.F.P. & S. Glasg. :—

B. D. J. van Rensburg, L. J. Wigston, P. H. A Gromelski, M. A. Walker, M. U. Ahmad, R. L. Chamberlain, Maurice Cohen, H. A. Bramwell, Alexander Reid, Euphemia Cardwell, A. E. Albuquerque, J. T. Cumming, W. C. Ross, Julius Meyer, M. M. Ghosh, J. B. Macdonald, M. M. El Hennawi, John Stewart, and M. J. Moynihan.

Royal College of Surgeons of England.

A meeting of the council was held on April 14th, with Lord Moynihan, the President, in the chair. Sir Henry Newland was introduced, and presented an address on behalf of the Royal Australasian College of Surgeons, of which he is president.

The following diplomas were granted :—

F.R.C.S.—H. O. Clarke (Dublin, Middlesex, and St. Thomas's).

M.R.C.S.—Sarah N. S. Barker (Leeds), A. L. Kenyon (Manchester), and R. S. Sandhu (Punjab).

D.T.M. & H.—Genesis Ameratunga (Ceylon), R. M. Buchanan (Glasgow), Dorothy D. Chacko (College of Physicians and Surgeons, New York), Jane G. E.-F. Cummins (Dublin), G. C. H. Franklin (Cooper Med. College), H. S. Gear (Witwatersrand), Amanda Hoff (Columbia), C. G. Hoole (Ceylon), S. R. Iyengar (Madras), Sirisena Petiyagoda (Ceylon), A. V. Pieris Ceylon), G. W. Puvimanasingham (Ceylon), Henry Richards (Guy's), John Rodger (Edinburgh), B. N [illegible] Silver (Maryland), Ramasawmy [illegible] Smith (Colorado), R. H. B. Snow [illegible] C. A. Stanley (St. Thomas's), R [illegible] Walcott (Glasgow).

Mr. J. H. Badcock (London) and Mr. H. B. Roderick (Cambridge), being members of the College of over 20 years' standing, were elected to the Fellowship.

The Jacksonian prize for 1931 was awarded to Mr. J. Paterson Ross, F.R.C.S., of St. Bartholomew's Hospital, for his essay on the Surgery of the Sympathetic Nervous System. *A certificate of honourable mention for an essay* on the same subject was granted to Mr. Lambert Charles Rogers, M.R.C.S., of the Royal Infirmary, Cardiff. For the year 1932 the subject for the Jacksonian prize is the *Pathology, Diagnosis, and Treatment of Diverticula of the* Large and Small Intestine, and for the year 1933 the Pathology, Diagnosis, and Treatment of Localised Rarefying Changes in Bones, as illustrated by Perthes' (or Legge's) disease, Schlatter's disease, Kümmell's disease, and allied conditions.

The President announced that the trustees of the late Lord Leverhulme had made a grant of £1000 for research scholarships, and proposed to allocate a similar sum in future years. A resolution expressing appreciation of the gift was unanimously adopted.

British College of Obstetricians and Gynæcologists.

The *quarterly meeting* of the council was held on April 11th. It was decided that in future the president, treasurer, and honorary secretary should be elected at the July meeting of the council, and take office at the autumn meeting. Prof. W. Blair Bell (Liverpool) was re-elected president until the autumn meeting of the council in 1932, when the maximum term of office allowed by the articles of association expires. The term of office of Prof. Munro Kerr *(Glasgow) having expired, Sir Ewen Maclean (Cardiff)* was elected vice-president in his stead. Dr. J. S. Fairbairn (London) was re-elected vice-president. Mr. Eardley Holland (London) was elected treasurer, and Prof. W. Fletcher Shaw (Manchester) hon. secretary. Dame Louise McIlroy and Sir Henry Simson were coöpted to the council until the next annual general meeting.

The President intimated that the extended time for acceptance of invitations to the foundation Fellowship or Membership had now expired (the Dominions and India excepted). It would now be necessary for all prospective entrants to the College to obtain the ordinary Membership. It was also announced that reference committees had been established *in Canada and India, and that all applications* for Membership from these Dominions would now be referred to these committees, and only candidates whose applications are endorsed by the respective reference committees would be permitted to take the examination for Membership.

At the *annual general meeting* on April 11th the following were admitted to the Fellowship :—

Trevor Berwyn Davies, Donald MacIntyre, Alexander Croydon Palmer, and Wilfred Shaw.

The following were admitted to the Membership :—

Elizabeth Grace Elspeth Baillie, Arthur Capel Herbert Bell, Alison Mary Hunter, Elinor Drinkwater Jackson, Ralph Lodge, Louisa Martindale, Charles David Read, William George Richards, and Albert Sharman.

It was announced that the following had been elected to the council to fill the vacancies caused by the statutory retirement of one-third of the members thereof :—

Representatives of the Fellows: Dr. J. [illegible] Sir Ewen Maclean and Prof. Miles H[illegible] Prof. J. M. Munro Kerr (Scotland). Members: Dr. C. P. Brentnall (Provinc[illegible] (Scotland); Dr. R. H. J. M. Corbet (Ireland).

The President announced that, through the help of an anonymous donor, the council has decided to purchase a home for the College in London. It was felt that the present satisfactory state of the College finances, and the help accorded by Lord Riddell, justified the undertaking, though it was fully realised that it was a big finan[illegible] responsibility. Lord Riddell's donation was for a period [illegible] seven years only, and efforts must be made to secure suffi[illegible] capital to replace it as a source of income at the end [illegible] this time. The opening of the College House would ta[illegible] place, if possible, on the same day as the annual din[illegible] in the autumn.

The meeting unanimously approved of a memoran[illegible] on the obstetrical and gynæcological training of med[illegible] students, prepared by the council for submission to th[illegible] General Medical Council.

Church Missionary Society.

The annual meeting of the Medical Mission Auxiliary of the C.M.S. will be held in the Central Hall, Westminster at 7 P.M. on Wednesday, May 4th. Field-Marshal Sir Claud Jacob will take the chair and the speakers will include Dr. H. T. Holland (Quetta), Mrs. C. Bacon, M.B. (Kweilin, Kwangsi-Hynan), and Mr. J. Howard Cook, F.R.C.S. Tickets may be obtained from the Superintendent, Lo[illegible] Department, Church Missionary Society, Salisbury-square, London, E.C.4.

Crystal Analysis.

The discourse to be given by Sir William Bragg at the Royal Institution conversazione on May 6th will be related to the various developments in pure and applied science which have depended on the use of the *X ray methods* of analysis [illegible] crystal structure. In order to supplement the discourse an exhibition is being arranged which will demonstrate more fully the work that has been done. Members of scientific *societies, senior students of universities* and technical institutions, and others interested in this work will be admitted if they present themselves at the Royal Institution, 21, Albemarle-street, London, W., between 10 A.M. and 6 P.M. *on Monday, May 9th,* or Tuesday, the 10th.

Reinstatement of Medical Man.

Some three weeks ago Dr. G. Staveley-Parker was dismissed from the honorary staff of Stamford Infirmary in consequence of complaints by the nursing staff of alleged breaches of rules of the contributory scheme. Last week by 25 votes to 20 the governors decided to reinstate him. A further resolution that the governors approved the action *of the staff of the infirmary* in bringing certain irregularities to their notice was put to the vote and lost. The committee of the benevolent fund of Rutland Engineering Works had threatened to withdraw their annual grant of £3[illegible] unless Dr. Parker was reinstated. It is reported that the Marquess of Exeter, president and chairman of the infirmary, and other governors, have since resigned.

Society for Relief of Widows and Orphans of Medical Men.

At a quarterly court of directors of this society, held on April 13th, Mr. V. Warren Low, president, being in the chair, *the death was reported of the widow* of a member who died in 1897; during this 15-year period she had received in grants £2120. Her husband had been a member for eight years and paid in subscriptions £10 10*s.* The expenses for the quarter were £84 17*s.* 6*d.* Grants to the amount of £166 5*s.* were voted—£91 to orphans who had reached the age of 16, at which age the ordinary grants cease, to enable them to continue their education or start in some professional or business career. One widow who applied for assistance was awarded a grant of £60 per annum with £50 per annum to each of two children. The annual general meeting of the society, membership in which is open to any registered practitioner who at the time of his *election is resident within a 20-mile radius* of Charing Cross will be held on May 11th. Particulars on application to the Secretary at the offices of the society, 11, Chandos-street, Cavendish-square, London W.1.

Contraceptive Clinics in Manchester.

The medical officer of health for Manchester, Dr. R. Veitc[illegible] clinics are being opene[illegible] and Crumpsall Hospita[illegible] methods of contrace[illegible] The medical officers, who are Dr. Olive Gimson an[illegible] Dr. Elizabeth Byrd respectively, will attend fortnightly f[illegible] sessions of two hours. The clinics are being provided, it [illegible] stated, in strict accordance *with the* Ministry of Health Memorandum, which required that instruction in contra-ceptive methods shall be given only in cases where *for medic[illegible] reasons* pregnancy is contra-indicated. Practitioners a[illegible] invited to send patients with a card or note of introducti[illegible] *stating the nature of these reasons.* The clinics *form* [illegible] integral part of the gynæcological and maternity section of t[illegible] hospitals, and are in no way differentiated from the ordina[illegible] hospital provision. They will be known as the mother[illegible] clinics, and attention will be *paid to the privacy* and comfo[illegible] of those who attend.

gnosis and Treatment of Venereal Diseases.

course of instruction in this subject begins this week he Municipal Clinic, 155, Regent-road, Salford. Meetings be held once a week.

adwick Lecture in Paris.

ir Humphry Rolleston, Regius professor of physic in University of Cambridge, delivered a Chadwick lecture Paris on April 8th. His subject was the Pioneers and gress of Preventive Medicine. Sir Humphry was cially welcomed by Dr. J. P. G. Meillère, President of Academy of Medicine of France, and after the lecture f. C. Hartmann and Prof. C. Achard spoke on the mmunity of public health ideals in the two countries.

rwin's House.

t is announced that the house and grounds of Down use, at Downe, in Kent, where Darwin lived for 40 years, open to the public without charge from 10 A.M. to 5 P.M. Sundays and weekdays alike.

blic Health in the Tropics.

A Chadwick lecture on the Educational Aspect of Public alth Work in the Tropics, with special reference to Kenya lony, will be given by Dr. J. H. Sequeira, late President the Kenya Branch of the British Medical Association, the council room of the Association, Tavistock-square, ndon, W.C., at 5.15 P.M., on Thursday, April 28th.

lking Films for a Hospital.

The Royal Devonshire Hospital at Buxton is to be ovided with a "talkie" apparatus at the cost of operators, many of whom are sent to the institution for eatment for gouty and rheumatic affections. The films ll be provided free of charge by a cinema company.

carcity of Young Doctors.

At the annual meeting of governors of Rotherham Hospital mment was made upon the scarcity of newly qualified edical men. It was stated that the hospital had spent 0 upon advertising and travelling expenses in connexion th medical appointments.

entral London Ophthalmic Hospital.

It was reported at the annual meeting last week that the w nursing home for private patients had already justified self by results. Small contributions by patients again creased.

resentation to a Surgeon.

On retiring from the active staff of the Royal Liverpool hildren's Hospital, after 32 years, Mr. R. C. Dun was last eek presented with a portrait of himself, given by ubscribers to the hospital and personal friends. He has een elected to the council of the hospital and appointed onsulting surgeon.

ayliss-Starling Scholarship.

Application is invited for this scholarship, of the annual alue of about £120 (with exemption from tuition fees) enable at University College, London. The scholar will e required to follow a course of study involving a training n the principle and methods of research in physiology nd biochemistry. Application must be made in proper orm by May 14th.

onference on Sterilisation.

A Conference on Voluntary Eugenic Sterilisation will be eld at the Caxton Hall, Westminster, on Monday, May 23rd morning and afternoon). The speakers will include Sir Thomas Horder, Dr. R. Langdon-Down, Mr. C. J. Bond, and Dr. C. P. Blacker. Particulars may be had from the ecretary of the conference, at 16, Mulberry-walk, London, S.W.3.

Invalid Children's Aid Association.

The annual meeting of this association will be held at 3 P.M. on Tuesday, May 3rd, at Crewe House, 15, Curzon-street, London, W., by permission of Lord and Lady Crewe. Lord Titchfield will take the chair, and the speakers will include Lady Snowden and Sir William Hale-White. The address of the Association is 117, Piccadilly, W.1.

Children's Hospitals.

The Children's Hospital, Paddington, received last year almost exactly the same number of in-patients, 792, as in 1930. They cost £3 14*s.* per week—a slight reduction; the 42,000 out-patients cost 7*s.* 10*d.* each. The children's parents voluntarily contributed £735.—Last week Major General J. E. B. Seely opened a new out-patients' department at the Invalid and Crippled Children's Society's Hospital at Plaistow, and the building was dedicated by the Bishop of Barking. Dr. F. G. Collins, medical officer of health for West Ham, expressed a hope that there would soon be a clinic where mental cases among the young might be treated.

Devonshire Hospital, Buxton.

The committee of management of this hospital have recorded their thanks to Dr. C. W. Buckley, Dr. J. B. Burt, and Dr. William Shipton for their 20 years of service on the active honorary medical staff and have asked them to give the hospital the benefit of their experience for a further five years. This invitation has been accepted.

Charing Cross Hospital.

Last year the income increased by over £4000, and the expenditure fell by £800. The new casualty department has been completed, further dressing-rooms, a waiting-room, and an additional fully equipped theatre have been provided, and the main section of the new nurses' hostel in Haverstock Hill, Hampstead, has been erected. The hospital has provided two private omnibuses for the conveyance of the nurses to and from the hostel.

Donations and Bequests.

Among other bequests the late Mr. Richard Foster Bolitho, of Gulval, Cornwall, left £10,000 each to the West Cornwall Dispensary and Infirmary; the South Devon and East Cornwall Hospital; and the Royal Cornwall Infirmary, Truro; and £5000 each to the Devon and Cornwall Sanatorium for Consumption, Didworthy; the Sanatorium for Consumption, Tehidy; and St. Dunstan's Hostel for the Blind.

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, April 25th.—8 P.M., ODONTOLOGY. Mr. W. Warwick James and Mr. Somerville Hastings: Mouth-breathing and Nasal Obstruction. A discussion will follow. LARYNGOLOGY. Members of the Section are specially invited to attend and to take part in the discussion.

TUESDAY.—5 P.M., MEDICINE. Short Papers: Dr. S. Harold Cookson: The Heart in Thyroid Disease. Dr. Adolf Schott (Bad Nauheim): The Respiratory Changes of Blood Pressure. Dr. A. Brian Taylor: Tuberculous Empyema. Dr. E. R. Cullinan: Dermatomyositis.

WEDNESDAY.—5 P.M., COMPARATIVE MEDICINE. Annual General Meeting. Short Papers: Dr. T. Hare: Demonstrations of Pathological Cases in the Dog. (i) Pituitary Adenoma with Dystrophia Adiposogenitalis. (ii) Neurocytoma of Suprarenal Gland. (iii) Fused Thyroid Glands. (iv) Aberrant Thyroid Tuberculosis in a Blackbird. Mr. A. B. Orr: A Note on the Incidence of Contagious Bovine Abortion in Great Britain. Dr. H. P. Bayon: Identical Primary Neoplasms (Nephromata) in Two Hens of the same Strain. Mr. J. T. Edwards: Rinderpest—Vaccination of Cattle with Goat-adapted Virus.

THURSDAY.—8.30 P.M., UROLOGY. Clinico-Pathological Evening. Cases and specimens.

FRIDAY.—Library closed at 5 P.M. 8.30 P.M., Reception. At 9.15 P.M., Dr. G. Norman Meachen will give a lecture-recital entitled Medical Musicians, illustrated by selections from some of their compositions.

HUNTERIAN SOCIETY.

THURSDAY, April 28th.—7.15 P.M. (at Simpson's Restaurant, Bird-in-Hand-court, E.C.), Annual General Meeting. Mr. James Ogden: Tutankhamen's Tomb. (Lantern lecture.)

MEDICO-LEGAL SOCIETY.

THURSDAY, April 28th.—8.30 P.M. (at 11, Chandos-street, Cavendish-square, W.), Mr. J. Bright Banister: The Gynæcologist in the Law Courts, to be followed by a discussion.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos-street, Cavendish-square, W.

FRIDAY, April 29th.—8.30 P.M., Prof. F. J. Browne: Maternal Mortality in all Cases of Pregnancy which have Received Antenatal Treatment. A Discussion will follow.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, London, W.

MONDAY, April 25th to SATURDAY, April 30th.—HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C. Course in Diseases of Children, mornings only.—INFANT'S HOSPITAL, Vincent-square, S.W. Course in Diseases of Infants, afternoons only.—MAUDSLEY HOSPITAL, Denmark-hill, S.E. Course in Psychological Medicine, afternoons.—LONDON LOCK HOSPITAL, Dean-street, W. Course in Venereal Diseases, afternoons.—CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL, Gray's Inn-road, W.C. Course in Diseases of the Ear, Nose, and Throat.—(These Courses are open only to Members of the Fellowship.)

WEST LONDON HOSPITAL POST-GRADUATE COLLEGE, Hammersmith-road, W.6.

MONDAY, April 25th.—10 A.M. to 1 P.M., Gynæcological Ward, Surgical Wards. Genito-Urinary Operations, Skin Department. 2 to 4 P.M., Operations, Surgical Wards. Medical, Surgical, Gynæcological, and Eye Out-patients. 4.15 P.M. (Lecture), Mr. Addison: Tumours of the Breast.

TUESDAY.—10 A.M. to 1 P.M., Medical Wards, Surgical Demonstration, Throat Operations, Dental Department. 2 to 4 P.M., Operations, Medical, Surgical, and Throat Out-patients. 4.15 P.M. (Lecture): Dr. Pritchard: Some Points in the Treatment of Gastric Ulcer.

WEDNESDAY.—10 A.M. to 1 P.M., Medical Wards, Children's Medical Out-patients. 2 to 4 P.M., Gynæcological Operations, Medical, Surgical, and Eye Out-patients, 4.45 P.M., Venereal Diseases Demonstration.

THURSDAY.—10 A.M. to 1 P.M., Neurological Out-patients, Fracture Demonstration. 2 to 4 P.M., Operations, Medical, Surgical, Genito-Urinary, and Eye Out-patients. 4.15 P.M. (Lecture): Mr. Davenport: Differential Diagnosis of a Red Eye.

FRIDAY.—10 A.M. to 1 P.M., Medical Wards, Skin Out-patients, Dental Department. 12 noon, Medical Lecture. 2 to 4 P.M., Operations, Medical, Surgical, and Throat Out-patients. 4.15 P.M. (Lecture): Mr. Vlasto: Pain in the Ear.

SATURDAY.—9 A.M. to 1 P.M., Throat Operations, Medical and Surgical Wards, Surgical and Children's Medical Out-patients. The lectures at 4.15 P.M. on Mondays, Tuesdays, Thursdays, and Fridays are open to all medical practitioners without fee.

ST. PAUL'S HOSPITAL, Endell-street, W.C.

WEDNESDAY, April 27th.—4.30 P.M., Mr. W. K. Irwin: Some Important Diseases of the Prostate.

ST. PETER'S HOSPITAL, Henrietta-street, Covent Garden, W.C.

WEDNESDAY, April 27th.—3 P.M., Mr. A. H. Harkness: Treatment of Chronic Gonorrhœa.

ST. MARK'S HOSPITAL, City-road, E.C.

THURSDAY, April 28th.—4.30 P.M., Mr. E. T. C. Milligan: Fistula.

HOSPITAL FOR EPILEPSY AND PARALYSIS, Maida Vale, W.

THURSDAY, April 28th.—3 P.M., Dr. Anthony Feiling will demonstrate.

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY.

WEDNESDAY, April 27th.—4.15 P.M. (at St. John's Hospital, 49, Leicester-square, W.C.), Clinical Cases. 5 P.M. Dr. Corsi: Onychia and Paronychia.

ROYAL INSTITUTION, Albemarle-street, W.

FRIDAY, April 29th.—9 P.M., Prof. H. Hartridge: The Rival Theories of Hearing.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

MONDAY, April 25th.—8 P.M., Prof. J. C. Drummond: Recent Researches on the Nature and Function of Vitamins. (Second of three lectures.)

MANCHESTER ROYAL INFIRMARY.

TUESDAY, April 26th.—4.15 P.M., Dr. W. Fletcher Shaw: The Price of Maternity.

FRIDAY.—4.15 P.M., Mr. W. R. Douglas: Demonstration of Surgical Cases.

UNIVERSITY OF BIRMINGHAM.

WEDNESDAY, April 27th.—4 P.M., Mr. C. J. Bond: Some Aspects of Human Biology. (Second of five William Withering memorial lectures.)

SALFORD ROYAL HOSPITAL.

THURSDAY, April 28th.—Dr. C. S. D. Don: Demonstration of Medical Cases.

VICTORIA INFIRMARY, Glasgow.

WEDNESDAY, April 27th.—4.15 P.M., Dr. W. Herbert Brown: Skin Cases.

Appointments

PRICE, MURIEL G., M.B., Ch.B. Belf., has been appointed part-time Medical Officer under the Belfast Maternity and Child Welfare Scheme.

SMITH, A. D., M.B., Ch.B. Edin., senior R.M.O., Sunderland Royal Infirmary.

Certifying Surgeons under the Factory and Workshop Acts: BARTON, N. J., M.D. (Borrowden, Rutland); RUST, F. P., L.R.C.P., L.R.C.S. Edin., L.R.F.P.S. Glasg. (Boroughbridge; W. Riding); ARMSTRONG, C. W. W., M.B., Ch.B. Oxf. (Framlingham, Suffolk).

Vacancies

For further information refer to the advertisement columns.

Aberdeen Royal Infirmary.—Hon. Asst. P.

Altrincham General Hospital.—Jun. H.S. At rate of £120.

Brighton, Royal Alexandra Hospital for Sick Children.—H.S. £100.

Brighton, Royal Sussex County Hospital.—H.P. £150.

Chesterfield and North Derbyshire Royal Hospital.—H.S. £150.

Colchester, Essex County Hospital.—Asst. H.S. £120.

Constance-road Institution, Dulwich, S.E.—Asst. M.O. £250.

Dalemere Forest, Cheshire Crossley Sanatorium.—Asst. M.O. £175.

Durham County Hospital.—Two H.S.'s. Each £150.

Ealing Borough.—Asst. M.O.H. £600.

Evelina Hospital for Sick Children, Southwark, S.E.—Ca and Out-patient Officer. At rate of £120. Also Anæsthetis 25 gns.

Halifax, St. Luke's Hospital.—Jun. Res. M.O. £250.

Hospital for Sick Children, Great Ormond-street, W.C.—Secretary. £750.

Hull Royal Infirmary.—H.P. for Sutton Branch Hospital. A rate of £160.

Ilford, King George Hospital.—Two H.S.'s. Each at rate o £100.

Ipswich, East Suffolk and Ipswich Hospital.—H.S. £120.

Kidderminster and District General Hospital.—H.S. £150.

Kingston-upon-Thames, Surrey County Council, Mental Hospital Service.—Jun. Asst. M.O. £350.

Leeds General Infirmary.—Hon. Asst. Physician.

Liverpool, Broadgreen Sanatorium.—Med. Supt. £900.

Liverpool Sanatorium, Delamere Forest, Frodsham.—Med. Supt. £250.

London Female Lock Hospital, 283, Harrow-road.—Asst. Non-Resident Surg. Reg. £50.

London Jewish Hospital, Stepney Green, E.—Res. M.O. and Cas. O. Each at rate of £150. Also Jun. Res M.O. At rate of £100.

Lowestoft, St. Luke's Hospital.—Res. Asst. M.O. £350.

Manchester, Abergele Sanatorium.—Jun. Res. M.O. £350.

Manchester, Royal Manchester Children's Hospital, Pendlebury.—Res. Surg. O. At rate of £125.

Maidstone, Kent County Ophthalmic and Aural Hospital.—Ophth. H.S. At rate of £200.

Minehead, Somerset, Minehead and West Somerset Hospital.—Res. M.O. At rate of £150.

National Hospital for Diseases of the Nervous System, Queen square, W.C.—Res. M.O. £200.

National Temperance Hospital, Hampstead-road, N.W.—Hon. Asst. Phys.

Northampton General Hospital.—H.S. to Ear, Nose, and Throat Dept. At rate of £150.

Oldham Royal Infirmary.—Two H.S.'s. Each at rate of £175.

Queen's Hospital for Children, Hackney-road, E.—Clin. Asst. for Med. Out-patients. 5s. each attendance.

Radcliffe-on-Trent, Notts, County Mental Hospital.—Second Asst. M.O. £450.

Reading, Royal Berkshire Hospital.—Two Cas. O.'s. Each £150.

Retford, Notts, Rampton State Institution.—Fourth M.O. £400.

Rochester, St. Bartholomew's Hospital.—H.P. and H.S. Each £175.

Royal Chest Hospital, City-road, E.C.—Res. M.O. and H.P. At rate of £150 and £100 respectively.

St. Alfege's Hospital, Vanbrugh-hill, S.E.—Asst. M.O. £350.

St. Mark's Hospital for Cancer, Fistula, &c., City-road, E.C.—Clinical Asst. for Out-patients' Dept.

Sheffield, Jessop Hospital for Women.—Hon. Pathologist and Hon. Bacteriologist.

Sheffield Royal Hospital.—Two Asst. Cas. O.'s. Also Res. Anæsthetist. Each at rate of £80.

Southampton Children's Hospital and Dispensary for Women.—Res. M.O. At rate of £100.

Wealdstone Parish.—District M.O. £100. Also Public Vaccinator.

Winchester, Royal Hampshire County Hospital.—H.S. At rate of £125.

Worcester County and City Mental Hospital, Powick.—Jun. Asst. M.O. £350.

Births, Marriages, and Deaths

BIRTHS.

HORDER.—On April 16th, at Ben-lui, Boyne Park, Tunbridge Wells, the wife of Cecil A. Horder, M.B., F.R.C.S., of a son

SMYTH.—On April 10th, 1932, at 22, Wimpole-street, W.1, to Esther, the wife of Michael J. Smyth, M.Ch., F.R.C.S.—a son.

MARRIAGES.

ORMEROD—PATERSON.—On April 16th, at Greenside Church Edinburgh, George Lawrence Ormerod, M.B., Westbury on-Trym, Bristol, to Violet Reid, youngest daughter o the Very Rev. Prof. W. P. Paterson, LL.D., University o Edinburgh.

RUSSELL—WOODWARD.—On April 16th, at St. Mary's Church Wanstead, Brian Russell, M.D., M.R.C.P., to Phylli elder daughter of the late Captain G. B. Woodward an Mrs. Woodward, of Snaresbrook.

DEATHS.

GRAVES.—On April 13th, at the Sussex County Hospita Brighton, Dr. Montague Graves, formerly of the We African Medical Service. Aged 46 years.

LOVEDAY.—On April 13th, suddenly, at Fleet, Hampshire William Dunmore Loveday, O.B.E., J.P., M.R.C.S., Hartfield-square, Eastbourne.

SALTER.—On April 17th, at d'Arcy House, Tolleshunt d'Arcy Essex, John Henry Salter, D.L., J.P., D.P.G.M. (Essex M.R.C.S., in his 91st year.

STEPHEN.—On April 11th suddenly, at Vordighera, Lieut Colonel Guy Neville Stephen, O.B.E., M.R.C.S. Eng D.P.H. Lond., in his 75th year.

STONHAM.—On April 16th, at The Maples, Catherine-road Surbiton, Henry Archibald Stonham, M.R.C.S., L.R.C.P D.P.H., aged 72.

WOOLLETT.—On April 12th, Charles Jerome Woollett, M.D F.R.C.S., of Ambleside, Streatham.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

THE CITY CORONERSHIP.

THE resignation of Dr. Waldo last month from his o coronerships (for the City of London and for the rough of Southwark) set in train various changes der the Coroners Acts. Section 4 of the 1926 t. which prospectively abolished every franchise onership as from the next vacancy, was expressly cluded from application to the City coroner; t Section 32 of the Act extended to the City coroner- ip, as from the next vacancy, all enactments relating borough coronerships. Thus in effect the City ronership ceases to have any special features except at it is still nominally a franchise coronership, and at it has special statutory jurisdiction under the ty of London Fire Inquests Act of 1888. As to uthwark, previously a franchise coronership for ich the City corporation made the appointment, d the London County Council paid the salary, the risdiction of the coroner will now be merged in the joining London coroners' districts and the franchise ll disappear. There still remains the franchise ronership of the Liberty of the Tower to which the nstable of the Tower has power to appoint, the ndon County Council paying the salary. The pointment of Mr. Danford Thomas, the existing roner for the Liberty of the Tower, to succeed r. Waldo in the City, brings these two adjoining anchises under the same officer's jurisdiction. The neral law being now applicable to the City, it seems at Section 31 of the 1887 Act (expenses of inquests the City and Southwark) has ceased to have effect. The result of these charges on the duties and emolu- ents of the City coroner's office appeared in the commendations made to the City Corporation by s Officers and Clerks Committee. The committee nsidered that the newly appointed coroner need not ive his whole time to his duties, and recommended at his salary be £700 a year, with £100 towards xpenses, exclusive of actual disbursements under the pproved schedule.

BLOOD TRANSFUSION APPARATUS.

A NEW apparatus for the transfusion of untreated lood has been elaborated during the last two years y Dr. Bürkle de la Camp, of Munich. The principle s similar to that of the older Kimpton's tube, but embodies certain notable improvements. The impton's tube was a vertical glass vessel holding 00 c.cm. of blood, clotting being prevented by an ner lining of paraffin wax. The blood entered rom the donor's vein through a needle at the bottom f the tube, and the flow could be encouraged by artially exhausting the vessel with a Higginson's yringe attached to the top. The needle was trans- erred to the recipient's vein, and the blood was llowed to flow in by gravity or could be assisted by eversing the Higginson's syringe and using it as a ump. The paraffin lining had to be renewed every ime the tube was used, and the process of renewal vas not easy. Unless the transfusion was effected apidly, clotting was apt to take place in the needle r at its junction with the tube, so that the operator ad to be an expert. The new apparatus eliminates hese difficulties. The vessel is made of a substance, atented under the name of Athrombit, which s said to be a condensation product of phenol and ormaldehyde, or "synthetic amber," and has been ound to have remarkable powers of retarding coagulation of the blood. It is transparent, hard, but not so brittle as glass, and is a bad conductor of heat, so that the contained blood does not readily cool. The second main advantage of the apparatus is the introduction of the Ainit needles. These are made of steel which is highly polished inside as well as outside, so that again clotting of blood in contact with them is retarded. The top of the vessel is closed with a three-way cock, so that the blood can be pumped into the recipient with a rubber bellows. The apparatus is beautifully finished, and the method appears to be a great improvement on the older one for use by those who believe it is important to have untreated, rather than citrated, blood. The only bar to its free use seems to be the price: for Athrombit is expensive, and there is considerable wastage in the process of making the vessels. The complete outfit is made with containers of two sizes, holding 300 and 600 c.cm. respectively, and the prices for free delivery in the United Kingdom are £15 15*s*. and £17 10*s*. We understand that the apparatus has been in use at the German Hospital for some time, and has given great satisfaction. It is sold by Mr. F. Walser, 269, Gray's Inn-road, W.C., who describes himself as sole agent for Great Britain and the Colonies.

MEDICINE AT SHANGHAI.

THE March number of the *Chinese Medical Journal*, published at Peking, contains an editorial on the Medical Aftermath of the Conflict in Shanghai. In this conflict, says the writer, have perished all the newly erected defensive fortresses of preventive medicine—the hospital of the National Quarantine Service, the Central Hygienic Laboratory, and all the laboratories and health stations operated by the public health department of greater Shanghai. Two well-known medical schools—Tung Chi and the National Medical Colleges—have also suffered considerable damage; and as all these works have been built up at great financial sacrifice their loss is almost irreparable. The article continues:—

> "Shanghai is also going to reap the whirlwind in another form. The overcrowding of the healthy and the sick in the already congested International Settlement present unusual difficulty for preventive medical control. This state of affairs may provoke at any time fatal outbreaks of contagious and infectious diseases from which the environs of Shanghai is seldom free. The public health department of the S.M.C. is not unaware of this danger. Assisted by the citizens' emergency committee, the department is taking all the necessary precautions, but its activities may not be able to reach those who are outside the war refugee camps. Weakened by want, depressed by the horrors of war, and disheartened by a hopeless future, these innocent victims of a 'defensive' war may prove defenceless against any imported virus (now that the National Quarantine Station and the health department of the municipality of Greater Shanghai have been rendered hors de combat) and start an epidemic. With all the hospitals, general and auxiliary, filled to overflowing, once under way it will be difficult to check and there is no knowing where and when it is going to end."

SEASONAL VARIATIONS IN CATS.

THREE workers, E. Armitage, R. J. S. McDowall, and S. N. Mathur [1] have been carrying out experiments on cats in order to establish that there is a seasonal variation in the response of the circulation in these animals to various procedures. They find that in spring the blood pressure rises independently of external temperature, that the respiratory rate is somewhat slower, the oxygen consumption lower, and the response to sensory stimulation increased. They come to the conclusion that all evidence points to the fact that the nervous system is more sensitive in spring; that the parasympathetic is reduced in activity is suggested by the deeper respirations, the constricted pupil, and the difficulty in obtaining reflex slowing of the heart on stimulation of the central end of the vagus at this time of the year. As an interesting corollary to this Sir Edward Sharpey-Schafer relates that when demonstrating in London he often failed to get cardiac inhibition or vagal stimulation, whereas in Edinburgh he was usually successful. He was at first inclined to put this down to difference in climate, but he remembers that he was in the habit of demonstrating this experiment in London during the autumn term and in Edinburgh during the spring term.

VACCINE PROPHYLAXIS IN A CHILDREN'S HOSPITAL.

AN experiment in Prof. Frölich's wards of the Rikshospital in Oslo is recorded by Dr. L. Stoltenberg,[1] whose observations cover two periods. The first, or control period, was between January, 1922, and March, 1925. During the second period, October, 1927, to May, 1931, all the children who were admitted to hospital and who showed no special contra-indication to inoculation, such as fever, were given subcutaneous injections of a polyvalent vaccine made from cultures obtained from the throats of all the children admitted to the Rikshospital over a considerable period. This period included epidemics of influenza as well as free intervals. As a rule, three injections were given each child at intervals of four days. The records of influenzal infections in the first control period were not as complete as in the second period, and the comparison was unfair to the prophylactic treatment, which, nevertheless, is held to have emerged with great credit. In the control period there were 496, and in the inoculation period 487 children. "Influenzal" infection was seen among 56 per cent. of the controls under the age of 1 year, but only among 12·9 per cent. of the inoculated children of the same age; the corresponding figures for children over the age of 1 year were 47 per cent. and 21 per cent. respectively. The incidence of influenzal complications told the same tale. There were 97 cases of bronchitis among the controls, and only 8 among the inoculated; there were 21 cases of pneumonia or broncho-pneumonia among the controls, and only 11 among the inoculated. Otitis occurred in 19 controls, and in 9 of the inoculated. As the incidence of the influenzal diseases showed no marked differences in Oslo in the two periods, it is thought that the comparative freedom of the inoculated children cannot have been due to a general decline of infective virulence.

NEW PREPARATIONS.

T.C.P. B^3 **COLLOIDAL EMULSION** (British Alkaloids' Ltd., Winchester House, London, E.C.) is another form of the T.C.P. preparation (trichlorophenylmethyliodosalicyl) described in THE LANCET of Jan. 11th, 1930 (p. 114). The new colloidal emulsion is intended as a medicament for internal employment in various intestinal conditions, and the percentage composition is given as follows: trichlorophenylmethyliodosalicyl, 1·00; tribromoacetyliodoorthooxybenzoic ac., 2·00; T.C.P. bismuthate, 1·50; colloidal aluminium silicate, 2·00; glycerin, 3·00; distilled water, 90·50. For adults a tablespoonful is taken morning and evening before meals in four tablespoonfuls of water; in acute cases the emulsion can be taken three times a day. The dosage for children is, according to age, from one to two teaspoonfuls in four to eight teaspoonfuls of water, morning and evening, before meals.

ELITYRAN (Bayer Products, Ltd., 19, St. Dunstan's-hill).—This is a preparation of thyroid for use in routine practice, but especially where intolerance has been shown to thyroid preparations generally. The claims of the manufacturers for Elityran over the B.P. preparation are that no unpleasant sequelæ follow, because exact standardisation enables the dosage to be gauged with precision. It is readily soluble, and is issued in tablets of 25 mg. each, in tubes of 30.

ADEXOLIN LIQUID (Glaxo Laboratories, 56, Osnaburg-street, London, N.W.).—A tasteless and odourless concentrated liquid which has been assayed and standardised to contain the vitamins A and D to an amount equivalent to 20 times its own volume in cod-liver oil. It is put forward as a means of administering the vitamins without the use, inconvenient in many cases, of cod-liver oil; for it can be given to persons with sensitive stomachs without producing digestive disturbances, while its use is indicated where there is fat intolerance and acidos The preparation is put up in 8 c.cm. bottles with a dropper affixed to the screw cap, and one drop from this dropper equals exactly half a minim. The suggested doses are, for infants, two drops added to three or more feeds a day; for children, six drops, three times a day with meals; and for adults, ten drops three times a day with meals; but the doctor may considerably increase the doses, if thought desirable, without apprehension.

CAPTURÈ OF WILD RABBITS.

ON an estimate made by Dr. A. H. B. Kirkman in a paper circulated by the University of London Animal Welfare Society,[1] hundreds of thousands of rabbits are tortured in traps every night throughout the winter, in Great Britain alone. The law requires that the traps should be visited once in the 24 hours, but in practice this is difficult to enforce, and in any case animals caught soon after sundown suffer until the next day. Were this the only method of ridding the country of animals regarded as vermin some arguments might be used in favour of it, but there is ample evidence that rabbits are largely regarded as game and preserved. A consensus of opinion obtained from the chief constables in the principal trapping counties is entirely in favour of humane methods and opposed to the use of the steel trap. Poachers make use of netting followed by immediate slaughter, and are able to secure numbers of rabbits in this way. Other humane methods recommended by Dr. Kirkman are the long net, the gate-net, the gate-trap and digging-out; but the method which can be most successfully and kindly used for extermination is poisoning by carbon monoxide gas, obtained from the exhaust pipe of a car and transmitted to the burrows by means of a garden hose. Hundreds of rabbits can be quickl and mercifully killed in this way, and though bodies are not accessible without digging, flesh is not made poisonous by the gas. A more or less humane methods he classifies the snare, the purse-net used with ferrets, and shooting with ferrets or with beagles and beaters. Th Rabbits Bill would give to the county councils power to intervene for the purpose of d rabbits where these have been allowed to mult to the extent of becoming a nuisance to and subclause 1 (7) would prohibit the use of spring trap. Dr. Kirkman suggests that the "spring trap" should bè replaced by "trap jaws adapted to grip the limbs," or "trap to inflict suffering."

INCOME TAX.

MR. W. R. Fairbrother, of Bush House, Ald London, writes: "Your readers may that during this month they will be receiving requiring returns of their income for 1932-33. will save considerable trouble if care is used in comp ing the forms in their entirety, and incidentally doing so your readers will be sure of having all the usual reliefs to which they are entitled. are cases in which less obvious adjustments can secured, such as relief from double as allowance for interest to bank or building soci and setting off loss in one business against profit another. An alternative to the last-mentioned to carry the loss forward, and a decision between two methods requires careful consideration to the loss of benefits by not taking full advantage of possibilities of each individual case. Those of yo readers who marry during the coming year, or ha done so during the past six years, should be to obtain the allowances due as from the date of ceremony, not forgetting that second marriages times give opportunity for claiming double child allowance in the year of marriage."

---

HOWARDS'

STANDARD

ETHER

NOTE.—This Anæsthetic Ether is of a higher standard of purity than that demanded by the British, German, U.S., Dutch, and Japanese Pharmacopœias, and the French Codex.

Laboratory reports show an average boiling-point range of **0·2 of a degree** and the tests for Aldehydes, Peroxides, etc., prove that *no purer or more consistent Anæsthetic Ether is available at the present time.*

Howards' Standard Ether is used by Government Departments and the principal Hospitals and Institutions throughout the Country.

USED IN MANY GREAT INSTITUTIONS, including:

London Hospital
King's College Hospital
University College Hospital
Westminster Hospital
Queen Mary's Hospital for the East End
Great Ormond Street Hospital
Royal Sussex Hospital
Oldham Royal Infirmary
Stafford General Infirmary
Paddington Infirmary
Freemasons' Hospital
Royal Waterloo Hospital
etc., etc.

HOWARDS' STANDARD ETHER IS NOW MADE FROM DUTY-FREE PURE RECTIFIED SPIRIT, AT THE SAME PRICE AS WAS FORMERLY CHARGED FOR ETHER PREPARED FROM METHYLATED SPIRIT

ADDRESSES AND ORIGINAL ARTICLES

ACUTE MASTOID DISEASE.*

SOMERVILLE HASTINGS, M.S. LOND., F.R.C.S. ENG.,
EGEON IN CHARGE OF EAR AND THROAT DEPARTMENT,
MIDDLESEX HOSPITAL.

T is important to remember that for practical poses all acute and chronic infections of the stoid bone follow disease of the middle ear. s possible that some cases of tuberculous mastoid y arise without previous otitis, and cases of hoid and syphilitic disease of the mastoid are o occasionally met with. A severe injury may rt mastoid trouble and I remember having clear out several mastoid as the result of shot wounds during the war. As a general e, however, we may say that mastoid disease is ceded by infection of the middle ear, though this y clear up completely before the mastoid infection ves evidence of its presence.

May I first of all recall a few points in the anatomy this region (Fig. 1). Infection of the middle ear ways takes place by way of the Eustachian tube, that as long as this tube is patent, whatever we may do to the mastoid or middle ear, reinfection can always take place. The mastoid antrum and cells may be regarded as diverticula from the middle ear, and whenever an acute infection of this cavity occurs there is pathological evidence that the mucous lining of the mastoid antrum and cells is also more or less involved. As a rule the mastoid cells get larger the further we pass from the antrum, the largest cell being usually in the mastoid process at its tip.

FIG. 1.

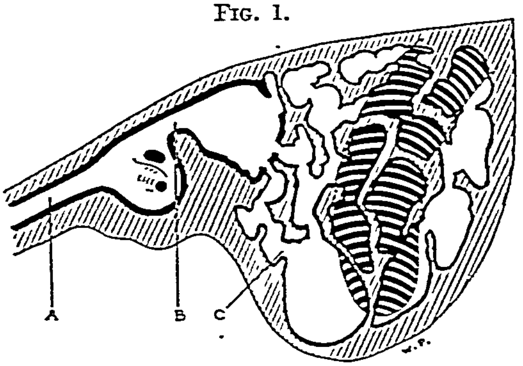

Diagram of structures involved in mastoid disease. From left to right are (A) Eustachian tube, middle-ear (B) aditus, mastoid antrum, and (C) mastoid cells covering the lateral sinus towards the right.

In very acute cases the mastoid infection may be so severe as to cause acute osteomyelitis of the mastoid bone. As a general rule, however, mastoid symptoms calling for surgical treatment only develop when pus is retained under tension, and for this to happen there must be obstruction at one of three points—viz., the Eustachian tube, the aditus, or the communication between the mastoid antrum and one or more of the cells Fig. 1, A, B, and C. Where the Eustachian tube is the seat of the obstruction, the mastoid symptoms will be relieved by a free incision in the membrana tympani. Where the obstruction is in the aditus and is not relieved spontaneously nothing short of opening the mastoid antrum will effect a cure. Cases in which the obstruction is situated between the mastoid antrum and the cells usually come on relatively late, and all trouble in the middle ear and antrum may have cleared up meanwhile.

The Decision to Operate.

Every practitioner must have seen cases of acute otitis in which infection of the mastoid antrum, as shown by tenderness behind the ear, has cleared up without operative interference. No doubt in such cases the pus contained in the antrum or cells has been evacuated via the aditus and discharged through a perforation of the membrane or down the Eustachian tube. It is also alleged that pus contained within a mastoid cell may undergo spontaneous absorption. It is certain that it may erode the bone, reach the surface and form an abscess, which may burst and slowly heal without any help from the surgeon.

A good many years ago when I first became interested in otology, a young woman appeared in my out-patient department with every sign of an acute mastoid. Her temperature was 102° F. and there was a brawny swelling behind her left ear. I explained to her the necessity for operation and painted a lurid picture of the dire results which would follow if she refused. She replied that she had two young children at home and no one to look after them, and that she was prepared to take the risk. Four months later she reappeared in my out-patient department to show me that she was still alive. Her mastoid was scarred but firmly healed and she explained that a linseed poultice had caused the abscess to burst, and that the sinus which remained had slowly healed.

Unfortunately, mastoid disease does not always spread outwards and thus reach the surface as in the case just referred to. Disease of the middle ear and mastoid may spread *inwards* producing facial paralysis, labyrinthitis, or meningitis; or *upwards* producing extradural abscess, abscess in the temporo-sphenoidal lobe of the brain, or meningitis; or *backwards* giving rise to pus around the lateral sinus or septic thrombosis of this sinus, meningitis in the posterior fossa, or a cerebellar abscess. It is less serious when the disease extends *forwards* into cells which are occasionally found in the zygoma, and in this way an abscess beneath the temporal muscle may result. Lastly, an infection of the cells at the tip of the mastoid may sometimes burst inside the insertion of a sternomastoid muscle and form that type of abscess tracking down the neck, which has been associated with the name of von Bezold.

A mastoid operation may have to be undertaken *to save life, to save hearing,* or *to save time:* to save life, by preventing the serious complications just described; to save hearing, because mastoid disease results in destruction or fixation of important structures in the middle ear. So that discharge which comes on acutely and still remains profuse after three or four weeks may sometimes prove a sufficient indication for a mastoid operation. We may also frequently save time by taking matters into our own hands and not leaving them to nature. When mastoid tenderness comes on after all symptoms of acute otitis have disappeared, it is pretty certain that resolution will not take place and the sooner a mastoid operation is performed the better.

It is, however, usually the possibility of serious complications that is the determining factor in deciding upon operation in most cases of mastoid

reas in meatal troubles it may be in front as l as behind the ear. In meatal troubles also, movement of the external ear usually causes ı and the movements of the jaw in mastication sometimes even painful, whereas the pinna can pulled forwards or backwards with impunity in stoid disease. The greatest help in diagnosis will, ever, be obtained by a careful examination of the atus. In mastoid disease there will be either changes he membrana tympani or a history of recent otitis, ereas in meatal infections, if a small speculum can pushed through the swollen meatus and the mbrana tympani examined, it will be found to normal. The real difficulty occurs in cases in ich a furuncle follows a neglected otitis, but the agnostic points just mentioned will usually make ings clear.

FIG. 2.

A boil in the left meatus simulating acute mastoid disease.

A post-auricular adenitis may also give rise to fficulty in diagnosis. The swelling is further back, ie external ear is not displaced, and the membrana mpani is normal. Further, a cause for the adenitis ich as an infection of the scalp or pediculi capitas ay be found.

During the war I saw a soldier who was the happy possessor a chronically enlarged post-auricular gland. Whenever was drafted for service in France, he would put a little ndensed milk in his ear, give the enlarged gland a thorough od rubbing to make the skin over it red, and report to his gimental medical officer. After he had been sent to me the base hospital as an acute mastoid for the third time, thought it best, for the honour of the profession, to excise ie gland.

A suppurating cervical gland just below the tip f the mastoid may also give rise to difficulty in iagnosis, especially if a chronic otitis with suppuraon exists as well. An incision will be necessary ı either case, and not *infrequently* when the abscess opened a small necrotic lymphatic gland will be ound surrounded by pus. Cellulitis or erysipelas ommencing in the mastoid region may give rise to emporary difficulty, as *may* also a suppurating ebaceous cyst, or a gumma. I once had to open a ubperiosteal abscess over the mastoid which came n a few *months* after typhoid fever. A pure culture f *Bacillus typhosus* was grown from the pus which t contained.

The Schwartze Operation.

Having decided, then, that an operation is necessary, 're have now to make up our minds what type of peration shall be performed. Whatever else is done he mastoid antrum must be opened, otherwise there s a possibility, or indeed a probability, of a second peration being necessary should another attack of titis media supervene. It is important also that every mastoid cell capable of giving trouble at any future date should be opened up as well. This is by no means always easy unless the situation of those cells which are especially liable to be missed is kept in mind. Mastoids vary very much in structure but certain cells are fairly constantly present and an attempt should be made to find and open up each of the following groups. In the cellular or pneumatic mastoid the largest cell is usually at the tip and this must in all cases be opened. Another important group of cells are found at what is called the sinodural angle—that is to say, at the point of junction of the middle and posterior cerebral fossæ. These cells are sometimes spoken of as the posterior superior group. Less constantly a group of cells extending into the zygoma above and in front are met with and at times these cells pass forward beneath the temporal muscle, and suppuration in them, if it spreads outward, forms an abscess beneath this muscle. A very important collection of cells which must always be searched for is the retrofacial group, deep to the facial nerve. Suppuration in these cells is liable to extend to the nerve itself, and I once saw a case in which meningitis leading to a fatal termination could be clearly traced to some of these cells left unopened at a mastoid operation done many years previously. The emissary or terminal cells, as they are sometimes called, are a superficial group, external or posterior to the lateral sinus groove. In searching for these cells it will be useful to remember that as a general rule the further we get from the mastoid antrum the larger the cells become, so that in opening up the cells of a pneumatic mastoid in a backward direction we cannot feel assured that we have reached the last until some fairly large ones are seen. Less frequently a group of cells—the marginal—are found inside the attachment of the digastric muscle.

The incision which I always make use of for the mastoid operation is made in the groove immediately behind the pinna. It diverges somewhat backwards below so as to be sure of missing the facial nerve. The advantage of this incision is the small amount of scarring that is left. Its disadvantage is the fact that in many cases there is not enough room to get to the most posterior cells through the incision. In this event, it is easy to make a cut at right angles to the incision, at about its centre, and this can be extended as far backward as is desired. My first incision goes through the skin only and the pinna is then dissected forwards and downwards until the cartilaginous meatus is reached. With a sharp knife a crescentic cut is now made immediately behind the cartilaginous meatus down to the bone, and a similar incision extends from the centre of this backwards as far as the skin edge, indeed a little beyond it if the skin is supple enough to be pulled back. With a periosteum elevator the periosteum is now separated from the bone and a mechanical retractor inserted to hold the periosteal flaps apart. Two or three cuts with a sharp chisel parallel to the surface of the bone usually suffice to open up the superficial cells, and unless there are strong indications otherwise, it is best to proceed at once to deal with the antrum, keeping as close as possible to the posterior wall of the meatus in doing so.

The lateral sinus groove is frequently opened in acute cases; very often indeed the disease has already eroded the bone and pus is in contact with the sinus wall. Whenever the sinus wall is seen, the opening in the bone should be immediately enlarged, as a small opening is a source of danger disease. Our object must be to operate early enough to prevent serious complications and late enough to be sure that the disease would not have cleared up had we left things alone. Whilst keeping these two considerations in mind, it is often very difficult in a given case to determine exactly when operation should be undertaken. Indeed it must be said that there are two schools of thought: those who operate early and those who operate late. My old teacher, the late Prof. G. Alexander, of Vienna, used rarely to operate before the sixth week after the commencement of otitis, and I used to wonder sometimes how he managed to hold his hand so long. On the other hand, there are people who open up the mastoid directly it becomes tender at any stage of the disease. There is no doubt that cases operated upon late usually seem to do better. The temperature generally falls rapidly, and the patient often suffers very few constitutional symptoms. On the other hand, it is equally true that one finds the dura of the middle or posterior cerebral fossa exposed much more frequently in the late operation and the way thus opened up for intracranial infection.

Signs and Symptoms.

In the diagnosis of mastoid disease calling for operation, four cardinal symptoms are usually described: *swelling*, *tenderness*, *pyrexia*, and *changes in the meatus*. Unfortunately, however, neither of them is constantly present. Whether there will be swelling of the mastoid or not depends to a considerable extent on the thickness of the bone over the mastoid antrum or cells. In investigating the point it is best to examine the patient from behind and to look out specially for a flattening out of the normal groove which exists between the pinna and the mastoid. Where the external plate of bone is thick, there may be no swelling, although disease is rapidly extending towards the meninges and brain. Tenderness is usually combined with swelling and when the two are present and the differential diagnosis is certain, operation is indicated except perhaps occasionally in the very earliest stages of the disease. Fever is a much more variable factor and of less importance diagnostically in acute than in chronic mastoid trouble. It may be absent entirely, where the disease is caused by *Streptococcus mucosus*; nevertheless, a continued rise of temperature to 101° or 102° after a free incision of the membrana tympani is very suggestive of mastoid disease requiring operation.

Most important perhaps of all are changes in the meatus, which must in all cases be carefully examined. It is best to inspect both before and after syringing, for wax and debris may easily be mistaken for bulging of the drum or posterior meatal wall. On the other hand if we examine only after syringing it is impossible to say whether the redness of the handle of the malleus is the result of syringing or of disease of the middle ear. *A sagging of the posterior superior wall of the meatus close to the drum indicates almost certainly that the disease has spread to the mastoid and that operation will be necessary.* In most cases in which the mastoid operation is under consideration there will of course be obvious changes in the middle ear: deafness, redness of the drum, or perforation and discharge, but it is very important to remember that while disease in the middle ear may have cleared up, disease in the mastoid may be advancing. It is extraordinary how rapidly middle-ear disease, even after a perforation of the membrane, may subside, so that operation on the mastoid may be called for

hearing, provided and only provided, th
history of middle-ear trouble a week or

In addition to these general indicatio
certain special symptoms which indicate t
of immediate operation. Grave toxæmi
tions of infection spreading inwards t
brain or paralysis of the facial or ext
muscles, come into that category as d
or convulsions in children, vomiting, or
a sudden and profuse discharge from th
a clear indication for operation.

I remember some years ago seeing a man
otitis a few weeks previously and whose ear d
not clear up. He was sent to me by a co

swelling behind the ear due to meatal t
on early, usually within a day or two of th
ment of symptoms, whereas except in th
cases, mastoid disease needing operatio
to develop. The displacement of the ea
troubles is said to be usually downwards a
whilst in meatal infections the ear is gene
forwards only. This sign is by no mea
as will be seen from the accompanying
(Fig. 2). Of more value is the fact that th

ost entirely abandoned in favour of the previous thod of taking the drug by snuffing.

t had been found necessary to set aside a certain mber of beds for the treatment of these malarial es in a ward detached from the main hospital lding, and when the malarial admissions ceased se beds were still maintained for the reception any heroin addict who might voluntarily seek mission for treatment to assist him in his attempt break off the heroin habit. The number of addicts king admission has always far exceeded the ailable accommodation, but no selection has been de.

The average length of stay in hospital of heroin dicts has been from 10 to 15 days, and various ethods have been tried for alleviating the dismfort of the patient during the withdrawal period. o attempt has ever been made to retain a patient hospital for treatment against his will, and this le appears to have a markedly beneficial effect on e mental attitude during the withdrawal period. has been observed that dissatisfaction shown y one patient with the treatment rapidly infects hers unless steps are immediately taken to check it; kewise approval expressed by a patient influences ose around him equally quickly, these patients eing very readily affected by suggestion. The sults obtained from any form of treatment in a mall series of cases may therefore be very misleading.

We have observed that the severity of withdrawal ymptoms on any given line of treatment does not lways bear a definite relationship to the daily mount of the heroin previously used or to the luration of the addiction, appearing in some cases o be affected most markedly by the mental make-up f the individual and his attitude towards this trying eriod.

The total number of these cases admitted for reatment from April, 1929, till the present date as been 461. Some of them apparently sought admission because through loss of occupation they could no longer afford enough of the drug to satisfy their wants. Many of them, however, came because of a genuine desire to break off the drug habit and, having done so, to keep off it for all time. A few seemed only to wish to break off the drug temporarily, since they realised that by so doing they could return to its use and once more for a time obtain the same pleasurable effect as they had originally experienced.

Methods of Administration and Types of Addicts.

Apart from the large number of intravenous heroin addicts studied in 1929, the usual method of taking the drug has been by snuffing, the daily amount being taken all at one time, or, more frequently, divided into two to four doses. No ill-effects on the nasal mucosa have been observed but in many cases the septum is found to be perforated as a result of a previous cocaine addiction at the time when cocaine was readily obtainable in Egypt. Occasionally one meets an addict who states that although snuffing is his usual method, he occasionally employs the intravenous or subcutaneous route to obtain either a greater effect from the same amount of the drug or a more immediate result.

The type of heroin addict we have had to deal with has varied very greatly. A number of them are obviously hereditary mental degenerates in whom it is apparent, from the first, that no benefit can result from any form of treatment; on the other hand a certain number are obviously extremely keen to get rid of the habit, which they realise only too well is ruining both themselves and their families. Apart from those found to be suffering from subtertian malaria, we have failed to observe any marked ill-effects on the physical condition of addicts as a result even of long periods of addiction with large doses. Some patients, because of having insufficient money to purchase necessary food, show marked signs of emaciation, but the majority are quite up to the average physical standard of non-addicts of the same class, and those showing emaciation rapidly regain their previous weight when given a suitable diet. This good bodily state indicates that the majority would be physically quite fit to resume their pre-addiction rôle in life provided they could be freed from the habit. The mental condition of these patients, on the other hand, shows marked impairment, their will-power being much weakened and their mental and moral standard much reduced. This mental change very markedly influences the response to treatment during the withdrawal period and subsequently. We have found no evidence to suggest that these addicts have indulged more than the non-addict in excess of tea or coffee before developing the heroin habit. The pupils of the heroin addict on first admission, while he is still under the effects of the drug, have not shown any abnormal contraction; they are usually moderately dilated and react normally to light. Constipation has not been complained of as a result of heroin addiction.

A Group of One Hundred and Twenty Cases.

A detailed study was made of this group of addicts to determine certain points of interest, such as the age, occupation, duration, amount of the drug taken, and the cause of addiction.

Age and occupation.—Of these addicts, 75 per cent. were between the age of 20 and 30 years, 15 per cent. between 31 and 40, and 10 per cent. above 40. Their occupations were very varied, but the largest number 23, gave their means of livelihood as street hawkers, an occupation which is not infrequently practised in Cairo solely as a means of allowing an individual a certain if not very honest means of acquiring sufficient money to enable him to indulge in his expensive dope habit; clerks came next 19, cab and taxi drivers 12, mechanics 10, carpenters and farmers 9 each, waiters 5, tailors, butchers, barbers, watch-makers 4 each, painters, students, cooks 3 each, ticket-collectors and journalists 2 each, and a policeman, a teacher, a typist, and a groom.

Daily dose of drug.—The daily amount of the drug used was difficult to arrive at with any degree of accuracy either from the weight of the drug taken or from the price paid for it, because heroin as sold in Egypt is usually adulterated to varying degrees and also the price charged by different traffickers seems to vary considerably. However, a very rough estimate was made from the addicts' statements of price and weight. Thirty-two considered that they were using less than 1 g. daily, 51 between 1 and 2 g., 14 between 2 and 3 g., 9 between 3 and 4 g., 5 between 4 and 5 g., 7 between 5 and 6 g., and 2 between 6 and 7 g.

Period of drug addiction.—Information obtained from this group of 120 addicts showed that the drug had been used for the following periods: less than one year, 20; one year, 5; two years, 14; three years, 10; four years, 7; five years, 17; six years, 14; seven years, 23; eight years, 12; nine years, 8; ten years, 3; more than ten years, 5.

Addiction to other drugs before heroin.—A history of no other addiction was obtained in 40 of the in case of bleeding. Should the sinus be injured or its wall so softened that it gives way, it will be necessary to at once obliterate the sinus by packing tightly between its wall and the bone. If the removal of bone has not been free enough it may be possible in trying to do this to block the external opening without obliterating the sinus, and in this case bleeding will take place within the skull, causing symptoms of increased intracranial pressure and even death. An increase in rapidity and decrease in volume of the pulse are warning symptoms, but if sufficient bone has been removed there should be no danger of this accident occurring.

Very occasionally sloughing of the sinus may take place after the operation.

I remember very well observing a grey patch on the sinus wall at a first dressing, two days after operation. While I watched it, the slough suddenly gave way and furious hæmorrhage took place. I packed between the sinus wall and the bone in both directions, but a rise in temperature to 104° six hours later, and a slight rigor, demonstrated the necessity for ligature of the internal jugular vein in the neck. Fortunately the patient recovered.

Where the middle cerebral fossa, or the lateral sinus groove has been opened, I usually prefer to leave the wound open at any rate, below, packing it with flavine 1 : 1000 and changing the dressings on the second day. We find that the pain of dressing can be much relieved by soaking the gauze packing in a little 5 per cent. Novutox just before it is removed.

Some surgeons claim good results by allowing the wound to fill with blood clot and sewing up completely; or by leaving bismuth iodoform paste in the wound. The first method appears to me contrary to all the principles of surgery, and I have had to remove so much BIPP inserted by other surgeons that I have made up my mind to put in none myself.

The Conservative Operation.

There is, however, a modification of the ordinary Schwartze operation described above, which I often make use of when the cranium has not been opened and no complications are to be expected. It was Küster, I think, who first recommended the removal of the posterior bony wall of the meatus almost to the level of the drum, but it was Charles Heath who introduced what he called the "conservative" operation for patients with chronic ear discharge. This operation I rarely find of value in chronic cases, but in acute mastoids it is really useful. The posterior wound is closed at once, and usually heals by first intention and the mastoid is drained through an enlarged meatus. In clearing away the bone no attempt is made to preserve the posterior meatal wall, which is removed almost to the level of the drum with chisel or cutting forceps. The cartilaginous meatus then tears away easily at the back, and the drum can be seen. A small scalpel is inserted through the meatus which is split along its lower border from within outward. The knife is then directed upwards at the junction of the meatus and concha, and before it is withdrawn the crus helicis is nicked. The posterior wall of the meatus can now be bent upwards and to help it to retain its position better it is wise to dissect off from it most of the cartilage, leaving, of course, the skin intact. It is usually now quite easy to insert the little finger into the meatus and this is replaced by a short length of soft rubber tube of the same size, which keeps the meatal flap in position. Looking through this tube the membrana tympani can be seen in the extreme front and the mastoid cavity behind, and through this tube the wound is packed with gauze. I usually retain the tube in the ear for about te days, changing it, of course, with each dressing, and at the end of this time if the posterior wound has heal the ear can be packed tightly with gauze, a piece of dry wool placed on top, and all bandages dispensed with. It is necessary to pack the wound tightly with ribbon gauze for several weeks while epithelium extends from the edges of the cut meatus, to cover in the granulations which have lined the mastoid cavity. This modification of the operation fo acute mastoid disease renders impossible the formation of a sinus behind the ear, which may take many months to heal, but as the dressing is apt to be a little painful until the tube is dispensed with, it is more suitabl for adults than children.

HEROIN ADDICTION IN EGYPT

AND ITS TREATMENT DURING THE WITHDRAWAL PERIOD.

BY A. G. BIGGAM, O.B.E., M.D. EDIN., M.R.C.P. LOND.,
MAJOR, R.A.M.C. (SECD. F.O.); PROFESSOR OF [illegible] EGYPTIAN UNIVERSITY, AND DIRECTOR OF MEDICAL UNIT, KASR-EL-AINI HOSPITAL, CAIRO;

MEDICAL TUTOR AT THE HOSPITAL;
AND
A. F. RAGAB, M.B. CAIRO,
MEDICAL RESIDENT REGISTRAR AT THE HOSPITAL.

SOME idea of the prevalence of narcotic
in Egypt can be obtained from a study of
Pasha's report[1] in which he shows that of 24
inmates of the State prison on Nov. 29th, 192
no less than 7130 had been convicted under the la
on narcotics—i.e., 5317 for possession of drugs
1813 for trafficking in them. He states that,
the majority of traffickers are themselves
at least one-quarter of the total population of
prisons are addicts. He considers that prob
these convicted persons constitute only 1 per
of the addicts of Egypt, so that there are
about half a million addicts in Egypt in a
of 14 millions.

Information acquired by the Central N
Intelligence Bureau of Egypt, from the
of 200 intelligent addicts, as to the nature of th
narcotics used in Egypt, shows that no less th
138 used heroin as compared with 20 using
14 hashish, 12 morphine, 8 manzoul, 6 mixtures,
2 cocaine.

We became especially interested in the study
heroin addicts early in 1929 owing to the
number of them admitted under our care
from high fever and marked ill-health brought ab
by infection with subtertian malaria. It
became apparent that all these heroin addicts f
to be suffering from malignant malaria had
employing the intravenous route for the
of their drug, and that the malarial infection
being transmitted from one addict to another
blood remaining in the syringe. A report on
malarial infection amongst drug addicts has al
appeared,[2] [3] [4] and consequently we shall only
here that the news soon got about amongst ad
that a risk was run in the employment of the in
venous method, and that this route has now

iptoms the sleeplessness was found in many cases persist to a marked degree and for a long period, l was not infrequently given as the cause of relapse er leaving hospital. The general weakness, mus- ar pain, and depression were also very persistent. thdrawals effects were most marked during the t three or four days but often continued to a ser degree for a month or more, the feeling of haustion often rendering the individual incapable resuming his occupation. Sneezing, yawning, l lacrymation were most evident during the first ee days, but sometimes persisted up to the seventh eighth day, or even longer. Colic, diarrhœa, usea, and vomiting were not usually severe during thdrawal, being complained of by less than half e patients, and where diarrhœa was present the mber of motions was never excessive, averaging m three to seven daily. The appetite was usually pidly regained after the intestinal symptoms had bsided.

Various Methods of Treatment.

Various lines of treatment were tried during the thdrawal period, the patients as far as possible ing kept in ignorance of them. The results were ry carefully recorded to enable us, if possible, form a definite opinion on their relative merits.

0 intravenous heroin addicts suffering from sub- rtian malaria were treated for their malarial infection, ie heroin being suddenly withdrawn in most cases, araldehyde being given as required, and in a few ses small amounts of morphine being added where ie condition of the patient made it desirable. The sults were good except that the patients often ffered considerable discomfort during the first ree days as a result of the sudden withdrawal. None showed serious cramps, convulsions, or respira- ory symptoms during the withdrawal period. Paral- ehyde was found a useful hypnotic, its taste and mell having a beneficial psychic effect.

On completing the treatment of the malarial roup, other groups were treated as follows: utohæmotherapy was carried out in 152 cases; lister fluid injections as recommended by Modinos n 40; normal saline injections as controls in 37; nsulin treatment in 20; and special substitution treatment in 102 cases.

AUTOHÆMOTHERAPY.

This mode of treatment had been extensively practised in certain skin and other diseases in some cases with favourable results, so not unnaturally it was considered worth a trial in the treatment of heroin addiction. Very encouraging results have been reported,[2] and we decided to try it in a series of cases so as to be able to form some definite opinion of its value in alleviating the withdrawal symptoms and in lessening the tendency to relapse after the withdrawal period. No selection of patients was made; patients were allowed as full a diet as they desired, their bowels were kept open, and they were encouraged to drink plenty of fluids. Blood was obtained from a superficial vein, usually in the arm, and injected deep into a muscle, usually in the gluteal region. Daily blood injections were carried out, the doses increasing from 2 c.cm. to 60 c.cm.; the course usually consisted of seven injections. The patients were blindfolded while the injections were being made and as far as possible kept in ignorance of the procedure. The immediate effect of an injection varied in different patients. Some who were previously restless and in great mental distress immediately went to sleep for one or two hours; but this sedative effect was merely psychic, for the same result was obtained by merely pricking the vein and injecting normal saline instead of blood into the muscle. Patients on autohæmotherapy were given paraldehyde and other sedatives at night where restlessness was marked.

The effect of blood treatment on the withdrawal symptoms varied markedly, according, as far as could be ascertained, to the patient's belief or otherwise in its efficacy. This belief was often influenced by good or bad reports on the treatment given by other patients who had already completed their course. Not infrequently a number of consecutive cases would be treated without complaining of any marked discomfort during the withdrawal period, but these might be followed by an almost equal number who showed the greatest distress and discomfort during the same treatment, no other cause apart from their mental attitude being discovered to account for the difference.

This treatment did not seem to influence in any way the tendency to relapse in spite of the claim of certain observers,[5] for even patients who had received very large doses of blood relapsed almost immediately after leaving hospital. The following is the record of one such case.

A male clerk, aged 28, had previously been addicted to alcohol and cocaine for one year, followed by heroin snuffed for five years, with an interval of heroin injections for two months; the daily dose was 1·5 g., and the cause of addiction sexual. The patient stated that he had previously been treated in a home run by two doctors in Heliopolis, but had relapsed at once after discharge because of pain in the bones, numbness, exhaustion, and sleeplessness. The general condition of the patient was moderate; his nasal septum showed an extensive perforation as a result of his previous cocaine habit.

Blood injections (autohæmotherapy) were given: on the first day 20 c.cm. were removed from a vein and put into the muscle of the buttock; on the second day 30 c.cm. were injected; on the third day 40 c.cm.; on the fifth day 50 c.cm.; this dose was repeated daily up to and including the eighth day. The withdrawal symptoms were marked colic, slight diarrhœa, lacrymation, sneezing, yawning, very poor sleep, and feeling of exhaustion. After the fourth day the symptoms improved, but sneezing, lacrymation, and yawning persisted to a lesser degree, and exhaustion and sleeplessness were still troublesome. The patient was discharged after 15 days still complaining of weakness. He reported within a month that he had relapsed owing to sleeplessness and the feeling of exhaustion.

After a very careful survey of the daily notes made during and after the withdrawal period—on 152 heroin addicts treated by blood injections, the results did not lead us to believe that this method of treatment had any special value in lessening either the withdrawal symptoms or the tendency to relapse. While certain patients on this treatment suffered little inconvenience during the withdrawal period, others who had previously taken the same amount of heroin over a similar number of years obtained little or no relief.

AUTOSEROTHERAPY (PHLYCTENOTHERAPY).

Modinos, working in Alexandria, read a paper in January, 1930, before the Egyptian Medical Society on a new line of treatment discovered by him for the cure of addicts; his treatment has since been commented on in certain journals.[6] He announced that in 1929 he had discovered, whilst treating patients for other diseases by blister fluid, that he had by chance cured them of their drug habit. His method is to apply a blister 8 cm. square to any region of the body, but preferably to the lower chest or upper abdomen, and after 12 to 14 hours to withdraw the serum from this blister, the amount varying from 5 to 20 c.cm. This he aspirates with a large bore needle and injects immediately, as it is, under the neighbouring skin; he recommends that group, and previous addiction to alcohol in 20, cocaine in 35, cocaine and alcohol in 12, and opium and hashish in 13. The addicts with a previous alcoholic and cocaine history not infrequently stated that they had first commenced using cocaine for its sobering effect after an overdose of alcohol, and that, once they had experienced the cocaine sensation, they persisted till heroin, becoming more easily procurable, took its place. The small number of addicts giving a history of previous hashish addiction is surprising in a country where smuggling of this drug is considered to be so prevalent, and might be taken to indicate that the hashish habit does not specially predispose to other more serious drug habits. Cocaine shows the highest figure for other previous addiction, but as this drug is now very difficult to obtain in Egypt addiction to it is seldom met except in those who, from their occupation or otherwise, have special facilities for obtaining it —e.g., two dentists were recently treated by us for the cocaine habit.

Cause of addiction.—The great majority of the cases of heroin addiction give as the reason for commencing the drug the fact that they had been informed that it had a marked sexual effect. They state that its chief effect is prolongation of the sexual act, but that this action is usually obtainable only for about a month or even less, being followed by a total loss of sexual desire and impotence. A few state that they have failed entirely to obtain any aphrodisiac effect, sexual desire being lost immediately. Some have stated that after they had ceased to derive any sexual effect they discontinued the drug for a time, and, on recommencing it, again obtained the initial sexual result. Most addicts state that, by the time the sexual action of the drug has ceased, it has usually become so essential to them that they cannot discontinue its use.

In the series of 120 cases here considered, 70 gave as the cause of addiction the desire for sexual effect; 34 stated that they commenced the use of the drug in order to forget their miserable existence or become oblivious of some mental worry; 7 took it to be companionable while sitting in a café with someone who was already an addict; 7 stated that they took it primarily to replace cocaine; one took it for sleeplessness and one to allay the feeling of fatigue. Not a single addict in the total of 461 cases stated as the cause of his addiction that the drug had first been ordered for some medicinal purpose by a doctor. It has also been very exceptional to get a history of the drug having originally been taken to allay the pain of some organic disease.

Withdrawal Symptoms.

During the treatment of all our cases careful daily records were maintained showing the symptoms complained of by each case during each day of the early withdrawal period. The majority of the addicts had had a dose of the drug immediately before admission and consequently showed little or no withdrawal symptoms during the first day. The first withdrawal symptoms to appear were usually psychic, with restlessness, excitability, and irritability in greater or lesser degree. A relationship between the intensity of these psychic symptoms, the dose, and the duration of the addiction was not always apparent, some severe cases of long standing showing these symptoms less markedly than more recent ones taking smaller doses of the drug. On an average, however, the long-standing cases suffered more severely during the withdrawal period. Within a few hours of the onset of unrest and irritability, physical symptoms began to appear, the most marked being sneezing, yawning, lacrymation, colic, diarrhœa, vomiting, and pains in the limbs; the intensity of these later physical symptoms was usually proportional to that of the initial psychic symptoms. Withdrawal symptoms reached their acme in one to two days, persisted unallayed for another day or two, and then, by the end of the third or fourth day, even without any treatment, usually showed definite signs of amelioration. This natural improvement after the third or fourth day, [illegible] wrongly attributed to some [illegible] and false hopes may consequently be based on this treatment.

Form Used for Recording Withdrawal Symptoms.

Day of admis. and treatment by B.F.I.	Gastro-intestinal symptoms.	Muscular (M) and nervous (N) symptoms.	Psychic symptoms.
2nd day 10 c.cm.	Sickness; vomit 3 times; colic + +; stools 6.	M. Weak. + + numb. + + pain legs and knees + + N. Lacry. + sneez. + + yawn. + +	Markedly excited, irritable, severe exh., slept 1 hour.
3rd day	Vomit 6 times; colic + +; stools 4 times; app. bad.	M. Pain knees + + weak. + + numb. + N. Lacry. + + sneez. + + yawn. + +	Excited, flushed face, staring eyes, marked exh., slept 1½ hours.
4th day	Vomit twice; colic + +; stools 4; app. bad.	M. Weak. + + numb. + pains legs + N. Lacry. + + sneez. + + yawn. + + headache +	Less irritable and excited but exh., slept 2 hours.
5th day 15 c.cm.	Vomit nil; colic +; stools 2; app. fair.	M. Musc. weak. + + N. Lacry. + sneez. + yawn. +	Mental state markedly improved still exh., slept 4
6th day	Vomit nil; colic nil; stools 2; app. good.	M. Weak. + Pain legs and knees + + N. Lacry. + sneez. + yawn. + headache +	Mentally quiet exh., slept 4 ho
7th day	Vomit nil; colic nil; stools 1; app. good.	M. Still weak. N. Lacry. + sneez. + yawn. +	Exh., slept 5
8th day 10 c.cm.	Vomit nil; colic nil; app. good.	M. Still weak legs. N. Lacry. nil, sneez. nil, yawn. +	Exh., slept 4
9th day	Nil.	M. Weak. + N. Nil.	Exh., sleep still n good.

App. = appetite; weak. = weakness; numb. = [illegible] lacry. = lacrymation; sneez. = sneezing; yawn. = y exh. = exhausted.

This case was under blister fluid treatment (B.F.I.). shows the maximum symptoms during the first three. as occurs in cases under no special treatment. With symptoms here show no amelioration from the blister treatment.

The withdrawal symptoms in order of freq and severity were: (1) sleeplessness and excitem (2) general weakness and pains in the muscles, [illegible] ally around the knee-joint; (3) sneezing, [illegible] and lacrymation; (4) headache; (5) colic, [illegible] nausea, and vomiting; (6) numbness and [illegible] in the extremities; (7) general depression, exhaus and irritability; (8) loss of appetite. Where [illegible] active treatment was undertaken to relieve th dually reduced, and the patient finishes all drug atment by the end of the seventh day. Occasion-, however, where a patient has shown any marked omfort during any stage of the withdrawal period, as been arranged that he shall have his previous 's treatment repeated instead of going on with the t day's reduction, but this change was seldom nd to be necessary.

his method of substitution treatment we consider st satisfactory, especially where the confidence the addict can be obtained, and it seldom fails make his withdrawal period comfortable. It ails very frequent treatment and many injections ramuscular or hypodermic, but this all tends have a beneficial mental effect on this type of lividual and is consequently more advantageous than ierwise. We have not found that these patients mplain of pain from the intramuscular injection 50 per cent. magnesium sulphate solution, as often curs when this solution is employed to increase the lative action of morphia in non-addict patients. a few cases luminal was given intramuscularly stead of orally, but no special advantage was served. The bowels were kept open during eatment, and a generous diet was allowed as soon as petite returned; patients were also encouraged drink plenty of fluids. No signs of any toxic fect were observed from the drugs used in this bstitution method of treatment, but no beneficial fect on the tendency to relapse appeared to result.

SPECIAL SUBSTITUTION TREATMENT.

First day.—8 A.M.: Luminal grs. 2. 9 A.M.: Morphine 02 g.; mag. sulph. 2 c.cm., 50 per cent. solution intra-uscular; strychnine gr. 1/200; atropine gr. 1/200 (½ amp. ich). 12 noon: Morphine 0·02 g., mag. sulph. 2 c.cm., 0 per cent.; strychnine gr. 1/200; atropine gr. 1/200. P.M.: Strychnine gr. 1/200; atropine gr. 1/200 (½ amp. ach). 6 P.M.: Strychnine gr. 1/200; atropine gr. 1/200; araldehyde draught 60 c.cm. (contains 4 c.cm. paral.). P.M.: Strychnine gr. 1/200; atropine gr. 1/200; morphine ·02 g.; mag. sulph. 2 c.cm., 50 per cent.; luminal grs. 2; il. colocynth. et hyoscyamus 2.

Second day.—6 A.M.: S.M.S. Eighth day.—6 A.M.: S.M.S. 90 c.cm.

N.B.—(*a*) If marked symptoms or signs of toxic effect from atropine or other drug are noticed, the dose should be reduced or discontinued. (*b*) Daily hot bath at 4 P.M.

We do not propose to consider here the questions of relapse or rehabilitation in drug addicts, where the mental make-up of the individual is so important. All we have attempted to do in treatment has been to study carefully certain methods for which claims of cure have been put forward and to state the results these methods have given in our hands. The results obtained from the sudden withdrawal of the heroin and the substitution of other drugs to replace it have given us such encouraging results that further trial of these methods seems indicated, remembering always the importance of gaining the confidence of the patient during any form of treatment.

Conclusions.

Heroin is much the most prevalent drug of addiction in Egypt, the habit seldom resulting from its administration for medicinal purposes, but usually from its repeated employment as an aphrodisiac. The habit, once established, necessitates the continuation of the drug long after all sexual effects have ceased. Addiction to heroin affects much more the psychic than the physical state of the individual, all the higher faculties being impaired, self-control diminished, and the addict becoming a mental and moral wreck. Some of the addicts studied by us, before acquiring the heroin habit, were hereditary mental degenerates, only too ready to fall a victim to any vice that might come their way; any line of treatment was almost certain to fail to benefit them. Others, however, were mentally quite normal before addiction, and in these the results of treatment were more encouraging. The physical condition of the addicts was, on the whole, surprisingly good, even despite a history of having taken the drug over prolonged periods.

The withdrawal symptoms were always more marked and troublesome during the first three or four days, and were influenced greatly by the mental attitude of the patient to, and his faith or otherwise in, the treatment being given. Some individuals had no real desire to stop the drug, while others were determined at all costs to do so, these latter appreciating and responding to any effort made to help them during the withdrawal period. Experiments with so-called "cures"—autohæmotherapy, autoserotherapy, and insulin—have in our hands failed to show any resultant benefit to the addict either during the withdrawal period or subsequently.

We have found, however, that the substitution therapy employed by us lessens the withdrawal symptoms very markedly, rendering this troublesome period comparatively comfortable in the great majority of cases.

NATIONAL HOSPITAL, QUEEN-SQUARE.—Last year this hospital received 1570 in-patients, whose average stay was 41 days, as compared with 47 days in 1930. The waiting-list was consequently much reduced The average weekly cost per occupied bed was £3 14*s.* 8½*d.*, an increase of 6*s.* 9½*d.* over the preceding year. Many of the buildings being old the cost of repairs is heavy, and expenditure exceeded income by £3485, little more than half the deficit of 1930. In the medical school the lectures and demonstrations have been attended by 384 men and women students from various parts of the world, and applications for admission to the school of massage are greatly in excess of its capacity.

the syringe should be at body temperature. He states that no reaction follows the injection, and advises that it should be repeated in four days, and again four days later. He recommends that sedatives should be given and the drug of addiction gradually reduced. He claims that the withdrawal symptoms are very slight, and states that he has cured many drug addicts by this method, the patients having no desire to return to the drug after discharge from hospital.

We had the opportunity of examining one of Modinos's patients treated on these lines, and this individual stated that he had been entirely cured of his heroin habit and had become as healthy as he had ever been before his addiction. This patient's account of his sensations during the treatment is interesting. He states that immediately after the first blister fluid injection was made on the right side of the body he felt quite strong on that side, the other half of the body however remaining as weak as before; the second injection was made a few days later on the left side, and at once both sides became equally strong and he felt quite normal. He stated that he continued to be sleepless for some days, but after a course of treatment by sedatives he became quite normal in all respects.

The cure in this case appeared to us from the history to have been brought about largely by suggestion. We decided to try a series of cases on this line of treatment and have now observed 40 cases under blister fluid medication, the fluid being obtained from a cantharides blister, usually applied to the lower chest or abdomen, the amount of fluid injected varying with the size of the blister from 5 to 20 c.cm., and the technique employed closely following that of Modinos. We found that the application of the blister usually caused considerable local pain and inconvenience to the patients, and the treatment was consequently not popular, many addicts asking to have it discontinued. We gave at least two and usually three injections of blister fluid with an interval of two or three days between each, but obtained no better results in the 40 cases so treated than in a series of control cases treated at the same time with the application of blisters, and the injection, not of serum, but of normal saline. We found that the withdrawal symptoms were not relieved, and that relapses occurred as frequently as with the cases on the normal saline treatment.

The following is the history of a case treated by us with autoserotherapy.

A male messenger, aged 30, had snuffed heroin for two years—probably 2 g. daily. There had been no previous attempt to stop the drug. The cause of the addiction was sexual. His general condition on admission was good, and the pupils were not contracted. Treatment commenced the day after admission; a cantharides blister was applied to the right side of the abdomen; 10 c.cm. of fluid were obtained and injected. Three days later a blister was put on the left abdomen and 15 c.cm. of blister fluid injected; three days later 5 c.cm. were injected. The patient complained of considerable discomfort as a result of the application of the blisters, and asked to have this form of treatment discontinued.

All the withdrawal symptoms were very marked and sedatives were required. The man left hospital after 15 days' treatment and reported again for further treatment a month later, stating that he had relapsed within a few days of leaving hospital.

We have now had a number of heroin cases under our care who stated that they had previously undergone blister treatment by Modinos and that they had relapsed very soon after completing the "cure." A careful study of our own cases has convinced us that blister fluid treatment carried on as nearly as possible on the same lines as Modinos has in our hands entirely failed to produce any beneficial effect in heroin addicts.

A SECRET REMEDY.

Treatment of heroin addicts has been carried out in a home in Heliopolis by two doctors, no accurate information being available as to the nature of the treatment. One case of heroin addiction was sent by us, at their request, to undergo their cure; he returned after five days to report that he was entirely cured, and again one month later to say that he had now relapsed and was as bad as ever. During the past two years we have had under our care a number of cases who have stated that they had previously undergone treatment by these two doctors, only to relapse soon afterwards. One group of five cases reported to us, stating that they had undergone the cure at Heliopolis under arrangements made by a high official in the Government service, and all five informed us that they had relapsed within ten days of completing the so-called "cure."

INSULIN TREATMENT.

Recently it has been stated that heroin addiction causes interference with the normal output of the internal secretions of the ductless glands, the pancreatic hormone being especially affected, and cl have been made that great benefit results in cases from the administration of insulin. We treated a series of 20 heroin cases with insulin, mencing with 20 units on the day after a and giving sufficient glucose to prevent hypoglycæmia. The same dose is repeated on the following day; on the third and fourth days 30 units of are given, on the fifth and sixth days 20 units are administered twice a day, and on the seventh and eighth days 25 units are given twice daily, the of glucose being increased proportionately. Sedatives have also been administered. We have been unable to detect any benefit from this line of tre the gastro-intestinal, muscular, and nervous sy being as marked as on treatment without and the feeling of exhaustion and weakness also uninfluenced. Blood-sugar estimations been carried out on these patients before com treatment, and no change from the normal h been found in their sugar tolerance.

SPECIAL SUBSTITUTION THERAPY.

A series of 102 heroin cases has been treated by on a special substitution scheme, heroin being sto at once and sedative drugs given to alleviate withdrawal symptoms. Under this line of treatment the patient can be kept comfortable and free from symptoms during the breaking-off. The sleeplessness which is usually such a marked distressing feature of the period following drawal can be completely relieved in 80 per of the cases, six to eight hours' sleep being obtain each night even during the first four days. N infrequently patients who were reported as n sleeping satisfactorily during the night were sound asleep on visiting them during the The 20 per cent. reported as not obtaining goo sleep usually slept for from two to four during the first three or four days after stop the drug. The gastro-intestinal symptoms we never troublesome on this substitution and were present in only about half the cases, then only to a very slight degree. Sneezing, yaw and lacrymation were very slight and caused li or no inconvenience. Under this scheme of treatment the sedative drugs, morphia, luminal, in muscular magnesium sulphate, and paraldehyde true acromegaly were absent in both, and active cretion of the breasts, with gross symmetrical largement in Case 1, were the only manifestations a functional disturbance.

OTHER PUBLISHED CASES.

A case occurring in a man, aged 43, presenting eatures similar to those described above, with both reasts enlarged and secreting milk, but with no ther evidence of endocrine disturbance, was described y Haenel. At autopsy, a tumour of the pituitary, escribed as an angiosarcoma, was unexpectedly ound. A number of cases in acromegalics are ecorded, but most of these are in women who have reviously been pregnant and have suckled infants, often at a period not far removed from the onset of ymptoms. Because of the ease with which secretion can be obtained from the breasts that have recently unctioned, most of these cases are of doubtful significance. Thus the patient recorded by Gajkiewicz n 1893 had well-developed acromegalic features, and secretion from both breasts. She had borne and suckled six healthy children, but had suffered from amenorrhœa for seven years before the onset of the symptoms. In 1896 Fazio described a similar case in an acromegalic woman who had weaned a child only a short time before coming under observation. More recently similar instances have been recorded by Maguire, Lodge, and Bab. Lactation in an acromegalic woman who had never been pregnant was described by Carnot and Bouttier. Acromegaly in the male with enlargement of breasts which did not secrete was noticed in a boy aged 18 by Shallcross. Roth and Henschen and Nager have recently added to the literature two instances of true secretion of hypertrophied breasts occurring in men suffering from acromegaly, and Bailey records an autopsy on a man suffering from gigantism, in whom the pituitary was grossly hypertrophied and the enlarged breasts contained excess of gland tissue.

It is now well recognised that lesions of the pituitary may produce manifestations resulting from disturbance of the vegetative centres in the hypothalamic area, and that possibly the reverse may also occur. In this connexion Riese's case, of a woman who developed secretion of the breasts as well as parkinsonism after an attack of epidemic encephalitis, is of particular interest. Riese considered that the mammary activity resulted from disturbance of the vegetative nuclei in this part of the brain. It has elsewhere been shown (Krestin) that changes in cutaneous secretion are a characteristic feature of post-encephalitis parkinsonism, and that these are probably associated with lesions of the hypothalamic region. As the breast is a modified cutaneous gland, the occurrence of such cases is, theoretically at least, not surprising.

Before discussing the relationship of the pituitary and mammary glands, the other endocrine conditions in which spontaneous lactation is known to occur may be mentioned. Disease of the ovary and testis forms the largest group. In ovarian conditions, enlargement of the breasts has been frequently observed as part of a generalised precocious or excessive somatic and sexual development. The cases such as those of Lucas, Southam, and Harris, were girls from 3 to 5 years of age who had sarcomatous or teratomatous growths of the ovaries, and who increased in stature out of all proportion to their ages, grew pubic hair, and menstruated. The breasts enlarged but were not observed to secrete milk. In Southam's and Harris's cases. removal of the growth was followed by a return to normal.

In males, gynæcomasty has been observed in a variety of lesions affecting the testis. Cooke described the case of a man, aged 26, whose breasts enlarged and secreted colostrum. At autopsy a chorion-epithelioma of the testis was found with secondaries throughout the body. An example of simple hypertrophy of the breasts without actual secretion in a man with malignant teratoma of the testis was also mentioned by Bailey. Of equal interest are cases of gynæcomasty associated with atrophy of the testis following trauma. Six such cases are recorded by Apert and Decléty, and one by Condomine. Whatsoever may be the physiological inter-relationship between the functions of the testis and breasts, that between the male genital tract as a whole and the mammary activity is illustrated by the occasional results of prostatectomy. Gynæcomasty following this operation is recorded in two cases—by Oppenheimer and by Kondoléon. Petit de la Villéon describes a similar instance in which a carcinoma occurred in one of the enlarged breasts.

Since considerable modification of the secondary sex characteristics is often a feature of tumours of the suprarenal cortex, alteration in mammary activity might well be expected in such circumstances. Actually, either hypertrophy or atrophy of the mammæ may occur. Holmes's case was that of classical virilism with atrophy of the breasts. Case 7 of Winkler's series was similar. Bulloch and Sequeira, however, record a girl, aged 11, who developed great obesity, the masculine type of hirsutes, cutaneous striæ atrophicæ, and enlargement of both breasts. As no mention is made of mammary secretion, it is probable that the breast enlargement was just part of a generalised macrosoma.

The appearance of female secondary sex characters is not a feature of suprarenal tumours in males. Weber. however, describes the occurrence of an extensive malignant hypernephroma of the suprarenal cortex of a man, aged 27, who developed enlargement of both breasts, from which milky fluid could be expressed. At autopsy both breasts contained active glandular tissue. A similar case in a young man whose breasts enlarged whilst the testes atrophied, with resulting impotence, was recorded by Bittorf. At the necropsy of this patient, recorded by Mathias, there was a malignant cortical hypernephroma with secondaries, and active secreting tissue in both mammæ.

Changes in sexual development are also known to occur in patients having pineal tumours. In most of the recorded cases, definite changes in the breasts were not usually found. In one case described by Oestreich and Slawyk, a psammosarcoma of the pineal in a boy of 4 years was followed by great increase in size as well as by great precocious development of the genital organs. The breasts enlarged a little and secreted colostrum.

DISCUSSION.

The significance of spontaneous lactation in lesions of the ductless glands is difficult to assess, since the factors controlling the normal physiological process are still imperfectly understood. Although in some of the recorded cases, particularly in those of cortical *suprarenal tumours*, the mammary changes may have been part of a generalised macrosoma, it was shown that in other instances, as in the pituitary lesions here recorded, a true excessive mammary activity was present, as distinct from a generalised body disturbance.

The control of normal lactation is probably chemical in nature, and takes place through the blood stream. The evidence excluding a somatic nervous control is conclusive (Golz and Ewald; Ribbert) and need not

SPONTANEOUS LACTATION ASSOCIATED WITH ENLARGEMENT OF THE PITUITARY.

WITH REPORT OF TWO CASES.

BY DAVID KRESTIN, M.D., M.R.C.P. LOND.,
PHYSICIAN WITH CHARGE OF OUT-PATIENTS TO THE DREADNOUGHT HOSPITAL; ASSISTANT PHYSICIAN TO THE LONDON JEWISH HOSPITAL.

NUMEROUS examples of spontaneous lactation in both sexes have been recorded, and its occurrence in animals is well known to veterinary surgeons. In most of these cases, however, the appearance of mammary activity in either sex was the response to a mechanical stimulus, the usual and most powerful one being suckling. Thus Knott records three unmarried nursemaids who had never been pregnant, and who, after repeatedly suckling their mistress's infants, secreted milk from their breasts. In each case the secretion ceased when the stimulus was removed. The youngest instance of this kind, recorded by Baudelocque, was that of a girl, aged 8 years, who suckled a baby brother for four weeks. Knott and others have also described the condition in the male. Heape discusses lactation in virgin bitches, and Marshall describes the production of mammary activity by regular mammary stimulation, in a mare which had never foaled.

Apart from suckling or mechanical stimulation, mammary activity, either in the male or virgin female, is usually associated with pathological changes in some part of the endocrine apparatus, association with disease of the organs of reproduction being most generally found. Obvious increase of mammary function, apart from pregnancy, is not a common feature of pituitary disease. For this reason a description of two such cases is given and followed by a brief résumé of the literature throwing light on the relationship of the ductless glands to mammary secretion.

DESCRIPTION OF CASES.

CASE 1, an unmarried woman aged 25, first came under observation in April, 1930. For some months she had noticed that the breasts seemed larger and heavier than usual, and for six months her attention had been directed to secretion from the nipples by the staining of her clothes. Pressure of either nipple readily and constantly produced a copious milky fluid, which at no time was blood-stained. Apart from a feeling of fullness and heaviness, there was no pain in the breasts.

For some years the patient had suffered from attacks of headache, usually frontal and occasionally temporal, generally coming on in the mornings. These had become more severe during the past twelve months, but the attacks were of short duration. Both vision and hearing were good. There was never any vomiting. The patient was always tall and well-built, but thought she had been getting bigger and heavier during the last few months. Records of height or weight were not kept. There had been no change in size of hats, gloves, or shoes. The skin was thought to be more coarse and more hairy than usual. The catamenia had been regular since the age of 14. Two years before coming under observation they became irregular, and six months later ceased completely; there has been amenorrhœa ever since.

The past history and family history were uneventful. The patient had never been pregnant. Both parents, brother, and sisters were all tall and of large stature.

The patient was well-built and healthy looking; weight 12 st. 8 lb., height 5 ft. 11 in. There was no undue prominence or enlargement of the bony ridges of the skull, lower jaw, hands, or feet. Conformation of the hard palate, teeth, and alveolar margins was normal. The tongue was not increased in size. Radiograms of the hands showed no abnormality of phalanges. The skin of the arms and legs was somewhat coarse and fairly hairy. Lineæ atrophicæ were absent. The pupils were equal and reacted briskly to light and accommodation. Fundi were normal. No ocular palsies were noted. The visual fields for white were full, those for red and green were somewhat contracted but within normal limits (Mr. A. Sorsby). No abnormality was detected in the cranial nerves or in the rest of the nervous system. The cardiovascular system was healthy; blood pressure 120/80. The lungs were clear. Liver and spleen not palpable. No abdominal tumour could be felt. The pelvic organs were normal and the hymen intact.

Both breasts were enlarged, heavy, and somewhat nodular, resembling those of a lactating woman; the skin over them showed a few enlarged veins. No tumour could be felt. Compression readily yielded a secretion resembling milk. A test-tube could be filled by the patient in two or three minutes from either breast. Qualitative analysis of the fluid showed the presence of fat, lactose, and casein as found in human milk. Microscopically the centrifugalised deposit contained numerous fat globules, a few leucocytes, and many granules resembling colostrum corpuscles.

The urine was normal in amount and contained no albumin or sugar. The Wassermann reaction was negative and the blood count normal. The blood-sugar curves after ingestion of 50 g. and 100 g. of glucose respectively were within normal limits, and sugar did not appear in the urine throughout these tests. Cushing's thermic reaction was negative. Skiagrams of the skull showed no obvious deformity of the lower jaw, and no enlargement of air sinuses. The sella turcica was enlarged in depth and in antero-posterior diameter. Measurements of sella: antero-posterior diameter 21 mm., greatest depth 17 mm., which exceed Cushing's maximum measurements for a normal fossa, namely 15 mm. and 10 mm. respectively.

The patient has remained under constant observation. She was placed on a restricted carbohydrate diet. For the first six months X ray therapy to the skull and to the breasts was tried without effect. During the next [illegible] months thyroid and whole pituitary gland was given by the mouth. The headaches have diminished in fre[illegible] and severity, and there has been a loss of weight of 15 [illegible] There has been no alteration in the general appearance or of the size of the jaw, hands, or feet. A recent [illegible] of the skull showed no noticeable alteration in the size of the pituitary fossa. For some time there was no appreciable change in the secretion from the breasts, but during the la[illegible] six months it has become definitely less.

CASE 2, a married woman aged 32, first came [illegible] observation in May, 1929. She had been married four [illegible] a half years, but had never been pregnant. The [illegible] had always been scanty and irregular, and had comp[illegible] ceased for thirteen months. About August, 1928, [illegible] noticed some pain in both breasts, which she thought [illegible] increased in size. A doctor whom she consulted about thi[illegible] expressed some fluid from both nipples, and sugge[illegible] pregnancy as a cause. Examination at a later date, [illegible] showed that the uterus was of normal size, as it was at [illegible] subsequent examinations. Soon after this, she [illegible] of severe frontal and occipital headaches, either [illegible] or throbbing in character, which would come on [illegible] once or twice a week and last most of the day. These headaches were not accompanied by nausea, and at n[illegible] time excited vomiting. Except for some general [illegible] and a rather worried state of mind (chiefly the result of her breast condition) there were no other symptoms. [illegible] was no alteration of the physical features, nor any [illegible] in size of the hands, feet, or head and face.

The patient was a bright and intelligent, well-built, and healthy looking woman; height 5 ft. 5 in., [illegible] 10 st. 6 lb., with a well-proportioned development of the whole body. The skin was smooth; striæ atrophicæ and excessive hirsuties were absent. Examination of the cardiovascular, respiratory, and nervous systems failed to reveal any abnormality. The fundi were healthy and [illegible] visual fields within normal limits. The urine was clear. Th[illegible] was no abnormality of the pelvic or abdominal organs.

The breasts, which were not disproportionately large, were pendulous, rather nodular, and a little tender on palpation. A thick, creamy fluid, microscopically possessing the features of colostrum, could be expressed from either nipple on slight pressure.

The skull was radiographed and, whilst the b[illegible] appearance and sinuses were normal, the pituitary fossa was distinctly enlarged. There was no erosion or a[illegible]tion of bone. Measurements for the pituitary fossa on [illegible] lateral radiogram taken under standard conditions (at [illegible] distance of 6 ft. from the tube) were 19 mm. and 13 [illegible] for the antero-posterior diameter and depth respectively. The patient's condition remained unaltered for [illegible] months, after which she left the country.

In both cases [illegible] of the reproductive apparatus, or [illegible] stimulation [illegible] be excluded with reasonable certainty. Althou[illegible] there was some doubtful alteration in the g[illegible] somatic development in the first case, the feature true acromegaly were absent in both, and active cretion of the breasts, with gross symmetrical largement in Case 1, were the only manifestations a functional disturbance.

OTHER PUBLISHED CASES.

A case occurring in a man, aged 43, presenting atures similar to those described above, with both reasts enlarged and secreting milk, but with no ther evidence of endocrine disturbance, was described y Haenel. At autopsy, a tumour of the pituitary, escribed as an angiosarcoma, was unexpectedly ound. A number of cases in acromegalics are ecorded, but most of these are in women who have reviously been pregnant and have suckled infants, ften at a period not far removed from the onset of ymptoms. Because of the ease with which secretion an be obtained from the breasts that have recently unctioned, most of these cases are of doubtful ignificance. Thus the patient recorded by Gajkiewicz n 1893 had well-developed acromegalic features, nd secretion from both breasts. She had borne nd suckled six healthy children, but had suffered rom amenorrhœa for seven years before the onset f the symptoms. In 1896 Fazio described a similar ase in an acromegalic woman who had weaned a hild only a short time before coming under observation. More recently similar instances have been recorded by Maguire, Lodge, and Bab. Lactation in an acromegalic woman who had never been pregnant was described by Carnot and Bouttier. Acromegaly in the male with enlargement of breasts which did not secrete was noticed in a boy aged 18 by Shallcross. Roth and Henschen and Nager have recently added to the literature two instances of true secretion of hypertrophied breasts occurring in men suffering from acromegaly, and Bailey records an autopsy on a man suffering from gigantism, in whom the pituitary was grossly hypertrophied and the enlarged breasts contained excess of gland tissue.

It is now well recognised that lesions of the pituitary may produce manifestations resulting from disturbance of the vegetative centres in the hypothalamic area, and that possibly the reverse may also occur. In this connexion Riese's case, of a woman who developed secretion of the breasts as well as parkinsonism after an attack of epidemic encephalitis, is of particular interest. Riese considered that the mammary activity resulted from disturbance of the vegetative nuclei in this part of the brain. It has elsewhere been shown (Krestin) that changes in cutaneous secretion are a characteristic feature of post-encephalitis parkinsonism, and that these are probably associated with lesions of the hypothalamic region. As the breast is a modified cutaneous gland, the occurrence of such cases is, theoretically at least, not surprising.

Before discussing the relationship of the pituitary and mammary glands, the other endocrine conditions in which spontaneous lactation is known to occur may be mentioned. Disease of the ovary and testis forms the largest group. In ovarian conditions, enlargement of the breasts has been frequently observed as part of a generalised precocious or excessive somatic and sexual development. The cases such as those of Lucas, Southam, and Harris, were girls from 3 to 5 years of age who had sarcomatous or teratomatous growths of the ovaries, and who increased in stature out of all proportion to their ages, grew pubic hair, and menstruated. The breasts enlarged but were not observed to secrete milk. In Southam's and Harris's cases, removal of the growth was followed by a return to normal.

In males, gynæcomasty has been observed in a variety of lesions affecting the testis. Cooke described the case of a man, aged 26, whose breasts enlarged and secreted colostrum. At autopsy a chorion-epithelioma of the testis was found with secondaries throughout the body. An example of simple hypertrophy of the breasts without actual secretion in a man with malignant teratoma of the testis was also mentioned by Bailey. Of equal interest are cases of gynæcomasty associated with atrophy of the testis following trauma. Six such cases are recorded by Apert and Decléty, and one by Condomine. Whatsoever may be the physiological inter-relationship between the functions of the testis and breasts, that between the male genital tract as a whole and the mammary activity is illustrated by the occasional results of prostatectomy. Gynæcomasty following this operation is recorded in two cases—by Oppenheimer and by Kondoléon. Petit de la Villéon describes a similar instance in which a carcinoma occurred in one of the enlarged breasts.

Since considerable modification of the secondary sex characteristics is often a feature of tumours of the suprarenal cortex, alteration in mammary activity might well be expected in such circumstances. Actually, either hypertrophy or atrophy of the mammæ may occur. Holmes's case was that of classical virilism with atrophy of the breasts. Case 7 of Winkler's series was similar. Bulloch and Sequeira, however, record a girl, aged 11, who developed great obesity, the masculine type of hirsutes, cutaneous striæ atrophicæ, and enlargement of both breasts. As no mention is made of mammary secretion, it is probable that the breast enlargement was just part of a generalised macrosoma.

The appearance of female secondary sex characters is not a feature of suprarenal tumours in males. Weber, however, describes the occurrence of an extensive malignant hypernephroma of the suprarenal cortex of a man, aged 27, who developed enlargement of both breasts, from which milky fluid could be expressed. At autopsy both breasts contained active glandular tissue. A similar case in a young man whose breasts enlarged whilst the testes atrophied, with resulting impotence, was recorded by Bittorf. At the necropsy of this patient, recorded by Mathias, there was a malignant cortical hypernephroma with secondaries, and active secreting tissue in both mammæ.

Changes in sexual development are also known to occur in patients having pineal tumours. In most of the recorded cases, definite changes in the breasts were not usually found. In one case described by Oestreich and Slawyk, a psammosarcoma of the pineal in a boy of 4 years was followed by great increase in size as well as by great precocious development of the genital organs. The breasts enlarged a little and secreted colostrum.

DISCUSSION.

The significance of spontaneous lactation in lesions of the ductless glands is difficult to assess, since the factors controlling the normal physiological process are still imperfectly understood. Although in some of the recorded cases, particularly in those of cortical suprarenal tumours, the mammary changes may have been part of a generalised macrosoma, it was shown that in other instances, as in the pituitary lesions here recorded, a true excessive mammary activity was present, as distinct from a generalised body disturbance.

The control of normal lactation is probably chemical in nature, and takes place through the blood stream. The evidence excluding a somatic nervous control is conclusive (Golz and Ewald; Ribbert) and need not be considered here. Whether the vegetative nervous system can be completely excluded from taking part —at any rate in disease—is by no means certain. Starling elaborated the view that normal lactation could be divided into two phases. During the first half of pregnancy it consisted of an anabolic or assimilatory process in which glandular hyperplasia and hypertrophy were prominent features. The second phase was a katabolic or disassimilatory process in which active growth ceased and milk was produced. The first phase was considered to be dependent upon the uterine contents during pregnancy, and could be artificially induced in virgin rabbits by the injection of fœtal extract (Lane-Claypon and Starling). By removing the uterus of the rabbit before the end of the first half of pregnancy, this phase can be terminated. Termination of pregnancy during the second half initiated the disassimilatory process accompanied by the secretion of milk. According to Starling, this results from the removal of the fœtal hormone. His results were confirmed by Foa and Biedl and Königstein. Halban considered that neither fœtus nor ovary were essential for lactation, and concluded that the placenta supplied the necessary stimulus. An important place has been assigned to the corpora lutea by Bouin and Ancel, who were able to effect an arrest of mammary development by destroying all the corpora lutea in pregnant rabbits. On the whole, much of the experimental evidence is contradictory, and definite conclusions cannot be reached.

In growths of the testis and ovaries, and especially the teratomata, the malignant cells may themselves behave like fœtal and placental elements. The cause of the gynæcomasty following on testicular atrophy or prostatectomy must remain a matter for speculation. There is no evidence that the suprarenal cortex has any direct effect on mammary activity. In most of the cases referred to in this group, the breast enlargement was probably part of a general increase in size of all the body and viscera. The known changes which occur in the sex glands in lesions of this kind may, however, provide some explanation for the appearance of true spontaneous lactation in some of the cases of cortical suprarenal tumour.

That there is some physiological association of the pituitary and mammary activity has long been recognised. Ott and Scott first demonstrated the galactogogic effect of secretion from the posterior lobe in a nursing goat, and this was confirmed by Schäfer and Mackenzie. The action of the posterior pituitary extract is to increase the secretion of an already active mammary gland, that is, to stimulate the disassimilatory phase. It cannot, however, initiate this activity.

In more recent years, evidence has accumulated to show that the anterior pituitary lobe can undoubtedly influence, and even induce mammary activity under experimental conditions. Whether it can do so independently or only in the presence of ovarian tissue, is still a moot point. Frei and Grüter, and Stricker and Grüter produced such activity, accompanied by lactation, in virgin mammals by the injection of anterior pituitary extract. They believed that it was necessary for the mammary glands to be influenced by a corpus luteum, the presence of which, however, was not essential at the time of making the injection. Evans and Simpson were able to show that this action was possessed by the aqueous alkaline extracts rich in growth hormone. With a similar extract, a combination of acromegaly and colostrum secretion was produced in a female dog by Putnam, Benedict, and Teel. These results were confirmed by Parkes who, however, was successful only in female animals in whom ovarian tissue was preserved, and he concluded that the anterior pituitary took effect through luteal tissue. It had already been shown by earlier workers that the presence of luteal tissue was not essential, and this has since been corroborated by Corner and Nelson and Pfiffner.

Thus there appears to be an established relationship between the anterior lobe of the pituitary and mammary activity, at least under experimental conditions. Whether the power to stimulate lactation is inseparably vested with the growth hormone, or whether a separate "mammary" hormone will eventually be isolated, is a matter which must await further experimental work. So far, mammary activity has not been induced by the use of the aqueous acid maturity-stimulating hormone isolated by Evans and Simpson. The possible influence of the important vegetative centres of the hypothalamic region has been referred to. The clinical and experimental evidence of this is too scanty to permit of any speculation regarding any direct effect on the mammary gland itself, or any indirect effect arising from the anatomical relationship of the pituitary to this region.

SPEECH AND INTELLIGENCE.

BY A. G. MORISON, M.D. ABERD., D.P.H.,
DEPUTY MEDICAL OFFICER OF HEALTH, BRISTOL.

CORRECT and distinct speech requires a definite ntal effort, and of this effort many aments are capable (Max Müller). Binet goes so far as to give classification of the mentally defective using speech his basis: idiots do not use words coherently, ibeciles use words but not coherent sentences, and e feeble-minded can use ordinary speech.

Speech is made up of words, and words are the mbols or counters of thought, only very limited ought being possible without speech or words. s one's speech is defective so probably has been e's intelligence—innate activity of mind, atten-on, memory, powers of association or ideation, and rtainly so is defective one's capacity for inter-ange of thought with one's fellows. As the result f the isolation so produced the possibilities of ucation are correspondingly limited.

DEVELOPMENT OF SPEECH IN MENTAL DEFECTIVES.

Some words are generally expected to be used by hildren about the age of 18 months, and a child s considered late in talking if there be not many ords in use by the third year.

I have recently reviewed 84 consecutive and ersonally-examined cases of mentally defective hildren. "Notified cases" are those of low grade—he idiot, imbecile, and feeble-minded notifiable to he local mental deficiency authority. "Certified ases" are of higher grade, the feeble-minded ot so notifiable. These 84 children commenced o talk according to the following Table (I.):—

TABLE I.

Commenced to talk at age—	At or just under 2 years.	2–3.	3–4.	4–5.	5–6.	6–7.	7–8.	8–9.	Still not talking.	Age not ascertainable.	Total.
Notified cases	3 or 8.8%	4	7	—	2	2	4	3	7	2	34
Certified	13 or 26%	12	16	5	—	—	—	—	—	4	50

TABLE II.

Age at date of observation ..	$5\frac{1}{12}$	$7\frac{1}{12}$	$7\frac{2}{12}$	$7\frac{7}{12}$	$7\frac{7}{12}$	$7\frac{9}{12}$	$7\frac{9}{12}$	$7\frac{9}{12}$	$7\frac{11}{12}$	$8\frac{1}{12}$	$8\frac{2}{12}$	$8\frac{2}{12}$	$9\frac{10}{12}$
Age when commenced to talk ..	4–5*	1½	2	2–3	2–3	1½	1½	2–3	2–3	2	2–3	2–3	3–4
Years been talking	1	5½	5	5	5	6	6	5	5	6	6	6	6

* This child proved to be educable in a special school and has therefore been included in the high-grade class.

The development of speech in most cases of mental deficiency is late; and the lower the mentality, the later tends to be the development of speech. The possibility of speech still being acquired by the low grades after a long waiting, even for eight or nine years, must be recognised.

Amongst the low-grade children, articulation was clear in only nine cases (26 per cent.), while it was slovenly, slurring, or jerking in character in five, and lalling in nine others. Speech was confined to one or two words in four children, and remained entirely absent in seven (only one being a deaf-mute). Twenty-five (50 per cent.) of the higher grade children had a normally clear articulation. Four were whispering children, and in two articulation was in a slow monotone. There was a hesitant stammer in one child, and the slovenliness of articulation due to enlarged tonsils and adenoids in another. One child was slurring in speech, while another, aged 5 years, who only commenced to talk three months before observation, showed a bulbar incoördination. Lalling was present in 13 children, to such an extent in two cases as to give idioglossia (so-called). In another, aged 15 years, the articulation was slovenly with clipping of words, again giving idioglossia. The remaining child at 6 years of age could say only a few words.

PARTICULAR DEFECTS OF SPEECH.

Lalling is the substitution of one consonant for another, and is common enough in the child who is just acquiring his speech. Its persistence in my cases has been noted in those who show a general mental inertia, and in another group of children who were proved to be defective in powers of general observation and attention. The persistence of lalling in the 13 higher grade cases is shown in Table II.

Lalling, then, tends to persist amongst feeble-minded children much beyond the normal. I have come to regard its presence of significance, although remaining certain that it is no pathognomonic sign of feeble-mindedness. I have noted it in several otherwise bright and normal children at the ordinary schools. Mental defect accounts for its persistence often enough, but it is equally true that some normal children retain their "baby-talk" to a much later period than the average. There is probably much truth in the insinuation that it may be seen in "those spoilt by improper training keeping them infantile" (J. Kerr).

Echolalia, on the contrary, I have never encountered except in the mentally defective. In this condition the child repeats the exact words addressed to him, or in extreme cases even words or phrases used in his presence, instead of giving an intelligent answer. It must be due to want of interpretation of the language spoken, indicating lack of any ability for or effort at thought at all, and be of the nature of an automatism. Six low-grade children and one higher grade child remained subject to echolalia, while one other higher grade child had now lost the stigma. "She used to repeat all we said to her without giving us any answer."

From one's speech can be gauged one's *stock of ideas*, and, to a less extent, the very nature of one's intellect. In the Stanford revision tests, at age 5, a child is expected to define in terms of use, or better than use, four of these words, chair, horse, fork, doll, pencil, table; at age 8 he is expected to define in terms superior to use, two of these words, balloon, tiger, football, soldier, and to know 20 of a list of 100 words which have been specially and methodically selected from a dictionary. In 37 (74 per cent.) of my certified children such tests alone would have given a mental age in agreement with that found by applying the complete scale of tests. In nine (18 per cent.) the estimates would have been too low, and in four only (8 per cent.) they would have been too high.

The usual meaning of *idioglossia* is a form of speech so defective, the consonants being so altered or so elided, or there being such a slovenliness of articulation, or such a clipping of words, that the afflicted appears to be talking a language peculiar to himself. This occurred in my idiots and imbeciles not at all, in the feeble-minded three times, and I have noted it in ordinary school-children on not less than ten occasions. It has been suggested that it may be due to some inherent inability to make prolonged use of the faculties of attention and observation which are necessary for the acquisition of correct speech (Leonard Guthrie). But in these ordinary school-children, if this be so, it has been the only evidence of any inherent weakness of attention and observation. Rather, it seems to be a motor affection, for it is certainly present in some otherwise normal children for some time after they have a complete sensory path for speech, for these children have normal understanding of normal spoken language. I can confirm the prognosis "it is invariably good" (J. Collier), and the observation "fortunately, improvement is steady once it begins" (Kerr.)

But the above "*idioglossia*" is not really an individual language and is entirely different from the idioglossia, a language of one's very own, which may be present in cases of congenital word-deafness. I have encountered five such cases in three years, four boys and one girl, two being brothers.*

In this condition, the peculiar speech appears to be the result of a partially developed lip-reading word, memory being accompanied by a normal acuity of hearing; and the prognosis is not invariably good, but depends on the mental capacity of the afflicted to respond to any special educational advantages which may come his way.

CONCLUSIONS.

There is an important relationship between speech and intelligence—the age of acquisition of speech, the nature of speech, articulation, the persistence of lalling, the presence of echolalia, there being also a peculiarly high value in a vocabulary test in the estimation of intelligence.

There are two connotations of the term "idioglossia." This phenomenon, however, is of little significance in the symptomatology of mental defect. For one type has not been present amongst idiots and imbeciles at all, has been found in normal school-children on ten occasions, and its prognosis is invariably good; and the other type, being the more true idioglossia, occurs in the congenitally word-deaf.

---

* A full account of these familial cases was given in the Jour. of Neurol. and Psychopath., 1930, xi., 28.

CLINICAL AND LABORATORY NOTES

NOTE ON THE REDUCING POWER OF β RADIATIONS.*

By Hector A. Colwell, M.B., Ph.D., M.R.C.P. Lond., D.P.H.

(*From the Barnato-Joel Laboratories, the Middlesex Hospital.*)

The actions of X rays and of the penetrating radiations from radium have generally been considered as essentially oxidising in character. The following observations show, however, that under some circumstances reduction occurs as a sequel to β radiation.

The experiments were all conducted upon liquid systems by immersion of thin-walled glass tubes containing radon. Except where otherwise stated small test-tubes measuring about 4·0 cm. in length by about 0·5 cm. in diameter were used as the containers. The radon tubes were usually of the order of 10 millicuries in strength, were of glass, about 2·5 cm. long, 0·5 mm. in diameter, and with a wall thickness of the order of 0·1 mm., thus allowing a large proportion of the β radiation to reach the liquid in which they were immersed. The volume of fluid taken for experiment was about 0·7 c.cm., that quantity being found to fill the test-tube to a convenient height and to correspond more or less with the upper limit of the radon tube when immersed.

During the experiments the mouths of the test-tubes were lightly plugged with cotton-wool to exclude dust. Except where otherwise mentioned, all proceedings were carried out at the ordinary room temperature, and each observation was checked by a suitable control.

METHYLENE-BLUE.

In the earliest experiments (which indeed first suggested the possibility of reduction as a result of radiation) a solution of methylene-blue (0·1 per cent. in H_2O) was taken, and in it was immersed a zinc-copper couple. After a day or two the original dark blue colour was nearly discharged. The resulting pale blue liquid on exposure to the air again gradually reassumes the original dark blue colour as a result of oxidation, while further reduction gives rise to complete bleaching.

Such a "partially reduced" methylene-blue solution (0·7 c.cm.) was pipetted off into one of the small test-tubes; the radon tube (10 mc.) immersed, the test-tube lightly plugged with cotton-wool, and the whole left for 24 hours. When re-examined, the colour was found to be completely discharged showing further *reduction*.

To test the matter further, the original (0·1 per cent.) methylene-blue solution was diluted (1 part to 9 of H_2O) so as to give a bright sapphire blue when placed in the small test-tubes. On similarly exposing this solution to radon of a similar order of concentration to that used in the first experiment (about 10 mc.), marked loss of colour occurred in the first 24 hours, followed by complete bleaching within a further period of the same duration.

Similar results were obtained with solutions of brilliant green, acid fuchsin, and safranin; in all of which loss of colour is indicative of reduction.

ALKALI, COPPER, SILVER, AND PICRATE SOLUTIONS.

The probability of reduction processes arising as a sequal to β radiation being thus established, three of the reagents commonly employed for the detection of "reducing" sugars—Fehling's solution ammoniacal silver nitrate, and picric-acid-caustic soda mixture were similarly irradiated. After the lapse of 24 hours obvious reduction had occurred in the silver solution, and the picric-acid-soda mixture was distinctly reddened.

The Fehling's solution showed no apparent change, and indeed did not do so when the time of exposure was prolonged to three days. But at the end of that time the test-tube containing it and the radon (together with a control s placed in an incubator at 35° C. The next morning a nt reddish deposit was seen at the bottom of the tube. is probable that the precipitation (not the original luction) was the result of the heat. The control showed evidence of change.

---

* The cost of this research was defrayed by a grant from the Medical Research Council.

In view of the fact that both ammoniacal silver nitrate d Fehling's solution are notoriously "tricky" in their actions, the experiments were repeated four or five times. variably reduction was found in the irradiated, while change was seen in the control specimens.

POTASSIUM PERMANGANATE.

The behaviour of solutions of potassium peranganate under similar conditions was next xamined. With centinormal $KMnO_4$ solutions radual decolorisation of the liquid with a muddy recipitate of MnO_2 resulted. With acid (H_2SO_4) olutions gradual decolorisation occurred, during hich the solution showed a tendency to assume a rown tinge. This was due to the presence of a very nely divided brown deposit, which gradually sank o the bottom of the tube, so that when decolorisaion was complete there was a small dark brown recipitate. This precipitate was formed when the oncentration of the acid was as high as five times ormal. On standing, it slowly diminished in uantity and in about a week had completely isappeared.

Experiments with manganous sulphate solutions showed hat exposure to β radiations was not attended by any recipitation of MnO_2.

On performing a further experiment with concentrations f N/100 $KMnO_4$ and 5N/1H_2SO_4, test-tubes of the same alibre (0·5 cm.) but greater length (7·0 cm.) were used, o as to accommodate 1·0 c.cm. of the acid permanganate solution. The radon tube was also increased in length to about 5·0 cm., while its radon content was of the order of 20 mc.

The same gradual loss of colour as before was noticed, but in addition four or five bubbles of gas were noticed adherent to the outside of the radon tube. The brown precipitate gradually formed and within a week after complete decolorisation had redissolved.

The gas bubbles suggested the presence of traces of hydrogen peroxide in the liquid, and indeed it has long been known that β radiations act upon water to produce traces of H_2O_2, and also that they decompose it when they act on it in dilute solutions.

To investigate the question of hydrogen peroxide formation, 1 c.cm. of distilled water was placed in each of six test-tubes (7·0 cm. × 0·5 cm.), and in each was placed a radon tube of the order of 20·0 mc. content.

After 24 hours, the first tube was tested for hydrogen peroxide by adding a drop of a saturated solution of titanic sulphate in concentrated H_2SO_4. On looking down the length of the tube and examining it against a white background a very faint yellow colour could just be detected, the control remaining colourless. On the five succeeding days one of the remaining tubes was examined, but the tint did not in any case seem deeper than that produced by 24 hours irradiation—i.e., the experiment suggested that equilibrium was soon reached when production and decomposition of H_2O_2 were balanced.

NITRATES.

As a final experiment upon the reducing power of β radiations it was decided to ascertain whether nitrates underwent any change to nitrites. As it seemed probable that a larger quantity of liquid than those used heretofore would be necessary the procedure was modified and an ordinary test-tube was used in which was placed the very thin glass tube (about 0·75 cm. in diameter and extending nearly the whole length of the containing test-tube) containing the radon.

The radon content was nearly 50 mc. The radon container was placed in the test-tube which was then filled with standard KNO_3 solution (1 c.cm. = 0·0001 g. N.) such as is used in water analysis. The radon tube was found to be buoyant in the liquid, so a slice of cork treated with paraffin wax was carefully slid over the mouth of the containing test-tube so as to keep it submerged, and the cork fixed in place by adhesive labels. After 24 hours irradiation the potassium nitrate solution was tested for nitrites by the Griess-Hosvay test (hydrocholic acid, naphthylamine hydrochloride and sulphanilic acid). A fine red colour developed, thus showing the presence of nitrites; the control test being negative.

Enough evidence has been given to show that at any rate when acting in confined systems of small content the β radiations give rise to definite reduction effects, and since the chemical changes produced by X rays and γ rays are usually considered as caused by the secondary β rays to which they give rise, it is possible that we may have here another step in the elucidation of the very complex question of the mode of action of radiations on living cells.

I have to acknowledge very gratefully the kindness of Prof. Tuck and Prof. Russ in affording me their valuable assistance, and also that of Mr. G. W. Spicer, B.Sc., in putting up the various samples of radon used throughout the experiments.

PREVENTION AND TREATMENT OF THE COMMON COLD BY "GLEGG'S MIXTURE."[*]

By E. P. Poulton, M.D. Oxf., F.R.C.P. Lond.,
PHYSICIAN TO GUY'S HOSPITAL.

I HAVE already described this treatment in a postgraduate lecture,[1] but as I have since modified the mode of application a second reference to the method is desirable, especially as no mention has been made of it in the recent discussion on the common cold at the Royal Society of Medicine,[2] and in subsequent correspondence in the *British Medical Journal*. The treatment consists in applying massive doses of an inert substance to the mucous membrane of the nose and nasopharynx. The mixture, which I have called "Glegg's mixture," consists of three parts of paraffinum liquidum, and one part of paraffinum molle (white vaseline), flavoured slightly with rosettol. By "Glegg's mixture with menthol" is meant the same paraffin and vaseline mixture containing gr. ½ of menthol per oz. of the mixture, without the rosettol. Both the mixtures are supplied under these names by the British Drug Houses in collapsible metal tubes for direct application. But undoubtedly the cheapest way is to order the material in bulk, and it will keep indefinitely in an airtight jar; 2 or 3 oz. at a time may then be transferred to a small stoppered bottle for daily use. The application is made by means of a "nasal pipette" (supplied by Down Bros., St. Thomas's-street, S.E.1), furnished with a strong rubber teat by which the mixture can be sucked up into the pipette. Between the applications the pipette is kept in a test-tube or small pot. It is important to see that the mixture is not sucked up into the teat, as this will cause the rubber to perish rapidly. These two methods are cleaner than using the nasal funnel described in my lecture. It is best for the patient to lie down on his back in order to apply the mixture, and a pipetteful should be driven down each nostril so that it is felt at the back of the nose; but it can also be applied standing up with the head thrown well back.

The method should be used if there is any fear that infection may have been incurred, or as soon as the slightest feeling of rawness at the back of the throat is felt. In slight cases the application should be made morning and evening; but at the beginning of a severe cold it should be applied four-hourly. If the treatment is delayed until the nose is blocked it may still be effective, especially if the mixture with menthol is used. In favourable cases the airway may be freed again after 24 hours or so, and the patient may be tempted to stop the treatment; this is a mistake, for the cold will return with its old severity in another one or two days; continuous treatment is necessary, although the number of applications can be quickly reduced after the first or second 24 hours.

---

[*] Abstract of an opening address in a discussion at the Hunterian Society, 1931.

[1] Post-Grad. Med. Jour., 1930, v., 75.

[2] See THE LANCET, Feb. 13th, p. 316.

I was first informed of this mixture by Mr. Wilfrid Glegg, F.R.C.S., in 1921; he devised it primarily for rhinological cases. Ever since that time I have used it for the prevention and treatment of coryza, and have recommended it to numerous patients and medical friends, and I have only come across one person who noticed no benefit. I do not wish to claim too much for this treatment; but I do claim that if the cold cannot be aborted entirely, at least it develops into a relatively mild affair. I have only once lost the sense of smell since beginning the treatment, and I feel certain that it prevents to a very considerable extent the spread of infection downwards to the bronchi. Possible disadvantages are that it may produce looseness of the bowels—this is commonly regarded as an advantage at the beginning of an infection—it is better not to swallow the mixture if it can be avoided; also it is a bit messy, and a good supply of handkerchiefs is desirable.

Having described the method a word is desirable as to the reason for its therapeutic action. I believe it acts because the mucous membrane, where the infection is situated, becomes coated with the oily mixture, and so proves a less favourable environment for the infecting organism. But if this point of view is correct a massive dose must be used. This view of its action also explains why oily sprays are so ineffective; the volume of the material is not sufficient. Before 1921 I always used a spray and dichloramine-T in particular; the latter was irritating to the mucous membrane and not effective, or it made the cold worse. At this time I was getting colds on the average once every six or eight weeks, and they ran their full course with a slight temperature. On arresting the first cold by means of this treatment the vicious circle seemed to be broken, and I did not get another cold for six months! There are various proprietary preparations on the market which might be considered of similar nature. These are inferior because either they are too liquid, being presumably made of liquid paraffin, or if the substance is a medicated jelly only a minute amount is taken. It is important to get the substance of right consistence; it should be so thick that it only just runs. I cannot speak so definitely on the subject of prevention as I have not had the opportunity of testing this on a large scale; but it would be very valuable to try daily applications of this mixture on half the occupants of a school dormitory during a period of colds, and to compare the incidence of colds among the treated and the untreated.

MEDICAL SOCIETIES

ROYAL SOCIETY OF MEDICINE.

COMBINED SECTIONS OF EPIDEMIOLOGY AND STATE MEDICINE AND DISEASE IN CHILDREN.

ON April 19th these sections held a joint discussion on

Infection in the Dormitory.

Sir HENRY GAUVAIN (President of the Section of Disease in Children) occupied the chair.

Dr. J. ALISON GLOVER, introducing the subject, said that in a residential school or institution infection could occur through many channels and in various places. The infection could be conveyed, for example, through tableware, pencils, pens, roller towels, or books; but breath-to-breath infection was the most common, the organisms being wafted in droplets passing from one individual to another. This process might obtain in dormitory, common room, classroom, changing room, study, dining-room, tuck-shop, hall or chapel, the frequency being in the order named. Except in girls' schools, where cubicles were almost universal, and in one or two boys' schools, the dormitory easily came first. But it had a serious rival, for during an epidemic of influenza or measles it seemed that many of the dangerous secondary infections due to hæmolytic streptococcus or pneumococcus were spread in the sick rooms and sanatorium wards. "Infection in the dormitory" might include that which occurred in washing places by the accidental interchange of towels. It was natural to regard bed-to-bed infection as important, since in bed the carrier and recipient remained in close proximity for nine to ten hours, and ventilation was lessened by the lack of movement of persons, by the closure of doors, and when stormy conditions prevailed, closure of windows too. Many children slept with open mouths, and so lost the protection of the nasal filter.

The most suitable diseases for the purposes of this study were those attributed to the hæmolytic streptococcus—i.e., tonsillitis, scarlet fever, and otitis media. In schools which had both day scholars and bo
the incidence of many infectious diseases was
found to be significantly less on the day scholars.
The variation of the incidence of a disease on different
dormitories was often significant. Where the ba
logical results of sample throat swabbings of
boys sleeping in a dormitory were charted,
groupings of carriers of the same organism or of th
same strain of the organism often pointed clea
to bed infection. When an epidemic of infe
disease broke out in a school, the first cases were
to the sanatorium or sick rooms. If the epidemi
was of considerable proportions, the sanato
accommodation was insufficient, and ordinary dorm
tories had to be adapted as sick rooms or war
Two dangers arose here: one was that the scho
authorities would not understand the perils of suc
adapted wards in epidemics of influenza or
which were generally accompanied by secon
infections if patients were crowded together;
should be spaced far more generously than 3 fe
between beds. Boys who showed any clinical si
of secondary infection with hæmolytic streptoco
should be at once removed from the ordinary measl
ward and nursed in special wards, or, preferably, i
separate rooms. Otitis media had been observed t
travel all down one side of a ward of a sch
sanatorium filled with measles convalescents. Oft
the Board of Education minima[1] were not attaine

cational Pamphlets. No. 86. 1931. Pp. 54, 56.

the avoidance of “dead space” in dormitories; the question of heating dormitories. The defect “dead space” was chiefly found in buildings not ginally intended as schools which had been adapted this purpose. Dr. Glover himself inclined to the heated dormitory, though the separate washing om should be moderately heated. Many of the ildren now came from centrally heated homes.

Surgeon-Captain S. F. DUDLEY's remarks were ade on the assumption that when people slept in ngested dormitories a large proportion of the fectious morbidity was contracted in bed. A mparison made of the attack-rates in two naval aining establishments, in one of which the sleeping nditions were denser than in the other, showed at while there was little difference in the attack-tes for the most infectious types of disease, the revalence of more serious infections and complicaons was higher in the establishment with the denser ight environment. This raised the question whether n improvement in sleeping quarters, too small to heck total morbidity, might not limit the clinical everity and the number of complications. The ontrast in the amount of sickness between trained en and recruits suggested the question whether y any practical methods the high morbidity among ecruits could be reduced without decreasing the high erd immunity of the trained men. Certain observaions seemed to suggest that institutional morbidity night be decreased by giving newcomers relatively nore space than older residents, or by grouping beds n dormitories, instead of having them all equidistant. When the spacing between beds was negligible it was mportant to aim at the greatest possible distance between one respiratory apparatus and the next. The principle of the grouping of beds was well worth experimenting upon, though such grouping would be unjustifiable in hospital wards. Captain Dudley suggested that parasites might be able to acquire new pathological attributes in closely packed dormitories. Observations on cases of close segregation at night favoured this possibility. One of the reasons why a dormitory had a bad name in the matter of infection was the custom of crowding closely round the fire or stove; proximity of beds was not always responsible. He advanced the view, which he held strongly, that much of the spread of disease was attributable to insanitary methods of washing up, which he called “dish-water infection,” and this applied also to the ordinary restaurant in civil life. The customary methods of washing all kinds of utensils were not satisfactory; even the rinsing of many glasses in the same water was culpable. This might well be an important means of spread of influenza, for some of the infective material must cling to the glass or cup after such careless methods of washing as were commonly practised.

Dr. R. E. SMITH (Rugby) said that the impression, widely held, that infection in schools was largely spread in dormitories required critical examination. Infection by droplet or by contact could very well occur in the study, in the school-house, in the chapel or classroom and in ordinary intercourse, and by carriers from outside the school. At Rugby there was an allowance of 66 square feet and a cubic capacity of 794 cubic feet per boy. In the studies the allowance was 31½ square feet. Space was not all that was required. Cross-ventilation in the dormitories was desirable, and the space available must be used to good advantage. Most epidemics at schools occurred in the Lent term, and their treatment formed a large part of the medical officer's duties. Measles conferred a lasting immunity, and the attack-rate was so high that he considered that the sooner the boy got it over the better for him. Influenza, however, conferred no immunity. He gave examples of infection by carriers, one being traced to a nurse who was brought in to nurse boys with scarlet fever and mumps. A carrier was dangerous for several days before infection, as well as during a number of days after it.

Dr. W. H. BRADLEY (Downside) spoke of the difficulty of investigating high velocity epidemics such as influenza and measles; in these diseases it was almost impossible to detect bed-to-bed spread, but variations in tempo and intensity in different dormitories suggested a dormitory factor. It was impossible to guess the ætiology of acute nasopharyngitis at the beginning of an attack. Most of his boys were admitted with a high pulse-rate and a subnormal temperature; about five hours later the temperature rose. For a long time both he and the nurses in the sick dormitories wore masks, and he was sure none of the nurses was instrumental in the spread. In many cases it was clear that relapse of so-called influenza coincided with a new infection by a distinct organism, a change in flora from non-coccal to hæmolytic streptococci having been demonstrated in the majority of relapses. He satisfied himself that at one time there were two distinct waves of infection operative in the school, and it was never safe to assume that the bacteriology was the same for the whole school. This assumption of uniformity was safe, however, if in any dormitory there was something clinically distinctive about all the cases. He agreed with those who attributed the main infection in schools to the dormitories, whether the infection were of high or low velocity; proper spacing of beds was of the utmost importance. He also spoke on the moral aspect of the question, and urged that the ideal to aim at was separate well-ventilated bedrooms.

Dr. DOROTHY TAYLOR (Bedales) said it was noticeable in big epidemics that all the complications came at the peak of the epidemic, and that was specially noticeable in otitis media and pneumonia. This she attributed to the increased virulence of the causal bacteria; the sanatorium was more likely to be crowded at the peak of the epidemic than at other times.

Dr. L. R. LEMPRIERE (Haileybury) said he did not wear a mask, and he had not had influenza for 30 years. The public school vaccine was projected with the idea of combating not influenza but its complications, and his own figures showed the incidence of the latter was reduced by its use. He described the dormitory arrangements in his school, and gave details of some outbreaks of infection. He had many times tried to trace infection by collecting the names of all possible contacts, not only in house and form, but by proximity in the gymnasium, chapel, and hall; but after the third, or even the second, batches the task became impossible. It had also been impossible for him to assign the chief cause of spread to the dormitory. He believed infection took place and spread far more readily in the house rooms than in the dormitories, for in the former there was the closest contact between the boys.

Dr. A. L. SUTCLIFFE (Malvern Girls' School) thought that as something like 100 per cent. of the population of public schools had measles, and they would have that disease sooner or later, it was a mistake to take the elaborate precautions against it which were now usual. He had never had serious complications following measles in any preparatory school with which he was concerned.

Surgeon-Captain P. M. MAY (Royal Hospital School, Greenwich) said that many of the scholars he had were already immune from measles, having had the disease at home. Seldom had he seen one boy take an infection of any kind from another. His beds were some distance apart, and the ventilation was quite good. He echoed Dr. Sutcliffe's question whether it was right to devote so much energy to prevention in preparatory schools.

Dr. ALICE SANDERSON CLOW (Cheltenham) said there were in Cheltenham 33 separate school establishments, and her conclusion was that the classrooms or day living rooms were the chief places for the spread of infection. She was able to establish a remarkable association between high ceilinged dormitories and very low incidence of infection, even though in such apartments the beds might be fairly close together. All her observation drove her to the conclusion that the chief danger was in stuffy classrooms.

Dr. F. W. GOODALL suggested that the difference in the incidence-rate of infection between boys and girls might be one purely of sex. In one public school epidemic he had found that though the small studies were only meant for one or two boys, it was not uncommon for a sort of committee meeting to be held in them, lasting most of the evening, when ten or a dozen boys sat with heads practically touching. There had been no supervision to guard against this custom, which alone would account for a rapid spread of infection.

Dr. E. P. POULTON spoke of the great efficacy in preventing the spread of infection of a massive application of an inert substance to the nasal and pharyngeal mucous membrane.[1]

The CHAIRMAN emphasised the great importance of abundance of fresh air everywhere; the more air the greater the dilution of the infecting medium and the less chance of infection. As a rule he did not think schools were properly planned; school, hospital, and sanatorium authorities had been too much at the mercy of the architect. He proceeded to describe the arrangement now being carried out at Alton, whereby the roof could be slid back and any desired side of the ward exposed to the fresh air and sun, while it was shielded from wind and rain in another quarter. The heating should be by the old Roman panel system, heating the floors, whence hot air rose and carried with it any infective material.

SECTION OF ODONTOLOGY.

AT a meeting of this section (to which members of the Section of Laryngology were specially invited), held on April 24th, Mr. E. B. DOWSETT, the President, being in the chair, Mr. WARWICK JAMES presented a joint paper compiled by himself and Mr. SOMERVILLE HASTINGS entitled

Mouth-breathing and Nasal Obstruction.

He said that for many years they had jointly examined patients suffering from conditions generally believed to be associated with mouth-breathing and nasal obstruction. The nose was the portal of entry for air in mammals, birds, and reptiles, and was the normal route in man. The powerful urge to breathe through the nose was present in everybody. They had examined 53 sleeping infants under a fortnight old, and all of them had breathed entirely through the nose, even if the lips were separated or the th was in the mouth. If the nose was pinched babies began to struggle and cry after abou seconds, and did not open their mouths until began to cry. In a case of congenital obstructi the post-nasal orifices recorded by C. W. Richar it had taken the child over two weeks to lea breathe through the mouth. It was surprising few children with perpetually open mouths used the oral route for respiration. Of 54 children tested, ten breathed by mouth in the time; seven used both nose and mouth; and used the mouth only. Oronasal breathing uncommon, and oral breathing was rare. there was no mechanical obstruction to m breathing, the urge to nasal respiration mu physiological. A full, deep inspiration could be much more easily through the mouth than th the nose, yet man and all animals used the Possibly continuous exercise of the sense of was of value to the organism, but more pro mouth-breathing animals had failed to s because of the protection afforded by the nose a throat and lung infections. In Sir Arthur opinion considerable changes had taken place nose and face since Roman times, mainly th diminished use of the masticatory muscles.

THE IDEAL MOUTH AND THE IMPORTANCE OF NE PRESSURE.

To understand what was pathological, i necessary to comprehend the normal mouth. tion implied a changing normal, but at any one it should be possible to conceive an ideal m most favourable to the *individual*. The i mouth was remarkably unformed compared that of the adult. The potentialities of existed, but the moulding of the parts was dependent on mechanical factors due to the of the muscles of the tongue, of mastication, expression. The eruption of the temporary provided a further mechanical stress. In the the ideal conditions were fulfilled when the were arranged in perfect alignment in r arches with the crowns free from the gum, was firmly attached to the bone, the thin being well protected by the overhanging b the enamel. The alveolar arch should be a mately as large as that of the dental crown vertical implantation of the roots. The oral should be free from air; the tongue should the area inside the dental and alveolar arch the lips and cheeks should be in close conta the outer side of the arches.

The most important factor in the develop the normal growing mouth and the preven local disease was the negative pressure produ the act of sucking or swallowing. From one litres of saliva were produced daily and de repeated acts of swallowing, which produced tive pressure of about 10 cm. of water. The tion also helped to keep the mouth healt removed food; in fact, a properly lubricated would hardly allow actual contact between f teeth and gums except on the crushing s If the anterior oral sphincter (the lips) fail loss of irrigation greatly favoured path changes in the front teeth thus exposed to If a negative pressure—however slight—was well-formed arches were found.

FAILURE OF THE ORAL SPHINCTERS.

If one of the sphincters failed, there was a expression in the face at rest; the nose was all, with a wide bridge; the alæ and cheek-bones re less prominent than usual; the nasal orifice s small and rounded or slit-like; the upper lip s short and everted, and the lower lip pendulous d thickened; both lips were often dry and cracked, d the chin small, receding, and "double." Often e mandible appeared to be displaced backwards; angle was not distinct, and its ramus appeared to relatively short. The nose was narrow internally, en with a deviated septum, and the turbinal icosa thickened. Failure of the anterior oral hincter was common but did not indicate mouth-eathing.

---

[1] The technique recommended was that described by Dr. Poulton on p. 933 of this issue.

Nasal obstruction was rarely caused by adenoids; ost of the children who benefited by removal of enoids had far too small a mass to cause any struction. In very few of the open-mouthed ildren was the airway through the nose less than at through the open glottis. The "adenoid facies" ight be present without any adenoids.

Negative pressure might be absent owing to the ilure of the anterior sphincter, the posterior hincter (the soft palate and tongue), or both. If e first, the loss of pressure was within the lips ly; the arches were rounded, the bite was too ose, and the mandibular incisors impinged on the alate. The upper incisors might project or even ope inwards. If, in addition, the tongue was not contact with the palate except at the back, the ont of the mouth was markedly deformed. If the osterior sphincter failed the deformity was less arked, but if both failed there was much deformity. he surfaces of the teeth were not irrigated and leaned by friction and always showed a deposit of ebris and tartar. When the mucosa and gums were ot compressed they became swollen and œdematous, nd a "tension ridge" appeared at the junction of ompressed and uncompressed areas.

CAUSES OF OPEN MOUTHS AND MOUTH-BREATHING.

The commonest cause of failure of the oral phincter seemed to be muscular weakness, often due o illness. Oral breathing might be demanded by espiratory distress, as in pneumonia, and a habit night start thus. There was often a familial failure of the anterior sphincter; imitation was an important actor. Lowndes Yates suggested as a probable ause a faulty position of the neck, the head being pressed forward. A superabundance of clothing, warm moist atmospheres, and the prone position all caused swelling of the nasal mucous membrane. At the junction of the naso- and oro-pharynx air drawn through the nose impinged on the pharyngeal wall. Adenoids might therefore easily become infected by germ-laden air, and attacks of nasal catarrh, with intermittent swelling of the nasal mucous membrane, might thus lead to oronasal breathing; further, hypertrophy of the adenoids might then produce oral breathing.

In congenital choanal atresia there might be few changes except in the palate, and those changes apparently resulted from absence of moulding by the tongue in consequence of the open mouth. Deformities of the nose and face seemed to be more the cause than the result of nasal obstruction.

DISCUSSION.

The PRESIDENT said the paper seemed to have inverted the usual arrangement of cause and effect. He asked whether developmental narrowing of the palate obstructed breathing.

Mr. T. B. LAYTON said it was important to keep separate the adenoid facies, the high, arched palate, and deformed dental arches. The typical adenoid facies was a myth for which no evidence had ever been brought forward. He thought the openers were rather trying to make the pendulum swing too far. Their paper showed what a dreadful word "adenoids" was. Very few people had a clear idea what they meant by it, and the ideas differed among different users. The operation on adenoids should seldom be done, and would in time pass into the limbo of forgotten industries. He would not accept the idea of an ideal normal. The number of factors in the upper respiratory tract was so great that it was impossible to collect statistical evidence. Very often the significant fact or case was far more important than a large number of insignificant ones. Mr. Layton showed illustrations of almost perfect palates associated with persistent mouth-breathing, and of high arched palate without contracted dental arch or "adenoid facies." Some condition involving the whole body, and not only the mouth and throat, underlay the facies: a condition called in recent work the "myasthenic state," the cause of which, in turn, lay not in one vitamin deficiency or one endocrine disturbance but in the whole hygiene of the patient's life.

Mr. A. R. FRIEL advocated giving children something to do with their mouths rather than just telling them to keep their mouths shut, and illustrated a little wheel for them to hold between the lips. To reduce the nasal congestion he used rubber bougies in the nose, causing the turbinate to shrink away and stimulating the nasal reflex.

Mr. A. LOWNDES YATES said that the paper commanded general agreement. He had found that whether a child breathed through its nose or its mouth depended on the position in which it lay. Children who lay on their backs sometimes had true asphyxial fits, like epileptic fits. If the head was thrust forwards there was a pull on the sphincters, which therefore worked less well. Scoliosis might involve anterior deformities of the head and something very like an adenoid facies. Adenoids caused congestion of the nasopharynx, which deflected the septum, and was followed by an increase in the size of the bony structure. Structures developing in an infected area could not develop normally. The reflex for nose-breathing was believed to be the passage of air through the middle meatus, and would act in the presence of considerable obstruction. Training a child in correct posture was generally of more importance than removal of the adenoids.

Dr. OCTAVIA LEWIN agreed that the conception of adenoid facies was without foundation, and cited a patient who had had "adenoids out five times," and still had the adenoid facies.

Mr. E. D. DAVIS stressed the value of coöperation between laryngologist and odontologist. The mouth-breather was not of such good physique as the nose-breather, and was a danger to himself and to others. The public should be educated to the fact that the odontologist's aim included utility and general physique as well as beauty.

Mr. C. SCHELLING suggested "labial valve" and "palatal valve" as better terms than "sphincter."

Mr. J. G. TURNER asked how negative pressure acted. He and Dr. Lack had long ago decided that the open mouth was no criterion of mouth-breathing. The fact in post-normal occlusion was that there was inferior retrusion of the mandible because there was not room for it between the upper canines; the maxilla was small. The retrusion might be associated following measles in any preparatory school with which he was concerned.

Surgeon-Captain P. M. MAY (Royal Hospital School, Greenwich) said that many of the scholars he had were already immune from measles, having had the disease at home. Seldom had he seen one boy take an infection of any kind from another. His beds were some distance apart, and the ventilation was quite good. He echoed Dr. Sutcliffe's question whether it was right to devote so much energy to prevention in preparatory schools.

Dr. ALICE SANDERSON CLOW (Cheltenham) said there were in Cheltenham 33 separate school establishments, and her conclusion was that the classrooms or day living rooms were the chief places for the spread of infection. She was able to establish a remarkable association between high ceilinged dormitories and very low incidence of infection, even though in such apartments the beds might be fairly close together. All her observation drove her to the conclusion that the chief danger was in stuffy classrooms.

Dr. F. W. GOODALL suggested that the difference in the incidence-rate of infection between boys and girls might be one purely of sex. In one public school epidemic he had found that though the small studies were only meant for one or two boys, it was not uncommon for a sort of committee meeting to be held in them, lasting most of the evening, when ten or a dozen boys sat with heads practically touching. There had been no supervision to guard against this custom, which alone would account for a rapid spread of infection.

Dr. E. P. POULTON spoke of the great efficacy in preventing the spread of infection of a massive application of an inert substance to the nasal and pharyngeal mucous membrane.[1]

The CHAIRMAN emphasised the great importance of abundance of fresh air everywhere; the more air the greater the dilution of the infecting medium and the less chance of infection. As a rule he did not think schools were properly planned; school, hospital, and sanatorium authorities had been too much at the mercy of the architect. The heating should be by the old Roman panel system, heating the floors, whence hot air rose and carried with it any infective material.

SECTION OF ODONTOLOGY.

AT a meeting of this section (to which members of the Section of Laryngology were specially invited), held on April 24th, Mr. E. B. DOWSETT, the President, being in the chair, Mr. WARWICK JAMES presented a joint paper compiled by himself and Mr. SOMERVILLE HASTINGS entitled

Mouth-breathing and Nasal Obstruction.

He said that for many years they had jointly examined patients suffering from conditions generally believed to be associated with mouth-breathing and nasal obstruction. The nose was the portal of entry for air in mammals, birds, and reptiles, and was the normal route in man. The powerful urge to breathe through the nose was present in everybody. They had examined 53 sleeping infants under a fortnight old, and all of them had breathed entirely through the nose, even if the lips were separated or the thumb was in the mouth. If the nose was pinched the babies began to struggle and cry after about 30 seconds, and did not open their mouths until they began to cry. In a case of congenital obstruction of the post-nasal orifices recorded by C. W. Richardson it had taken the child over two weeks to learn to breathe through the mouth. It was surprising how few children with perpetually open mouths really used the oral route for respiration. Of 54 such children tested, ten breathed by mouth in the day-time; seven used both nose and mouth; and three used the mouth only. Oronasal breathing was uncommon, and oral breathing was rare. Since there was no mechanical obstruction to mouth-breathing, the urge to nasal respiration must be physiological. A full, deep inspiration could be drawn much more easily through the mouth than through the nose, yet man and all animals used the nose. Possibly continuous exercise of the sense of smell was of value to the organism, but more probably mouth-breathing animals had failed to survive because of the protection afforded by the nose against throat and lung infections. In Sir Arthur Keith's opinion considerable changes had taken place in the nose and face since Roman times, mainly through diminished use of the masticatory muscles.

THE IDEAL MOUTH AND THE IMPORTANCE OF NEGATIVE PRESSURE.

To understand what was pathological, it was necessary to comprehend the normal mouth. Evolution implied a changing normal, but at any one period it should be possible to conceive an *ideal normal* most favourable to the individual. The infant's mouth was remarkably unformed compared with that of the adult. The potentialities of growth existed, but the moulding of the parts was largely dependent on mechanical factors due to the action of the muscles of the tongue, of mastication, and of expression. The eruption of the temporary teeth provided a further mechanical stress. In the adult the ideal conditions were fulfilled when the teeth were *arranged in perfect alignment* in rounded arches with the crowns free from the gum, which was firmly attached to the bone, the *thin margin* being well protected by the overhanging bulge of the enamel. The alveolar arch should be approximately as large as that of the dental crowns, with vertical implantation of the roots. The oral cavity should be free from air; the tongue should occupy the area inside the dental and alveolar arch, while the lips and cheeks should be in close contact with the outer side of the arches.

The most important factor in the development o the normal growing mouth and the prevention o local disease was the negative pressure produced b the act of sucking or swallowing. From one to tw litres of saliva were produced daily and demande repeated acts of swallowing, which produced a negative pressure of *about 10 cm. of water.* The irrigation also helped to keep the mouth healthy. I removed food; in fact, a properly lubricated mout would hardly allow actual contact between food an teeth and gums except on the crushing surface If the anterior oral sphincter (the lips) failed, th loss of irrigation greatly favoured pathologic changes in the front teeth thus exposed to the ai If a negative pressure—however slight—was presen well-formed arches were found.

FAILURE OF THE ORAL SPHINCTERS.

If one of the sphincters failed, there was a lack o expression in the face at rest; the nose was usual cognised. It had been found that the earlier zema passes into the flexural prurigo, and that thma begins to be noted at about four or five years age. Ichthyosis to a greater or lesser degree was ways present. The skin condition tended to clear puberty, but the asthma remained. Most of the patients were sensitive to something—usually to ood proteins—and it was interesting to note that the rst signs appear about the time that foods other man milk are added to the diet. Wheat was commonly a factor. Two cases under his care were the ollowing:—

---

[1] The technique recommended was that described by Dr. Poulton on p. 933 of this issue.

> A girl, aged 14, had almost every conceivable treatment. he was put on a wheat- and egg-free diet, and was free from sthma for four weeks. On adding wheat and eggs the sthmatic attacks returned. She is now again free on the estricted diet.
>
> A boy, also aged 14, showed ichthyosis, patches of prurigo f the Besnier type, and a typical asthmatic chest with great ntero-posterior widening and indrawing of the lower ribs. He lived on a farm and was sensitive to cattle hair. In hospital he was free from attacks. He was also kept on a wheat-free diet.

These cases, said Dr. Freeman, were usually stated o have achlorhydria. One of these reported had, and the other had not. The basal metabolic rates were low.

Dr. CYRIL MURPHY mentioned a case of asthma in which the patient was sensitive to dog's hair. Her dog was given away and she remained free from asthma. Recently however she had come in contact with dogs, and the asthma had returned. He was now treating her with injections of dog's hair antigen and the result was very satisfactory. He thought that wherever the offending protein could be avoided, it was possible to bring about a cure of the disease.—Dr. W. G. HARVEY referred to the use of auto-hæmotherapy in these cases, and said that he had found proteose injections useful in many conditions, but not in asthma.—Dr. ABRAHAMSON laid stress on the importance of a careful history. Without it the skin tests were often confusing and misleading.

Dr. FREEMAN in replying said that it was almost impossible to cure asthma in elderly people, or in cases which arose from infection in the lungs. The only cases in which it was possible to obtain really good results were young people, and cases in which the offending protein could be eliminated. He had found auto-hæmotherapy of use in cases of pruritus, but not in asthma.

Dr. O'CONNOR read a note on Some Cases of Artificial Pneumothorax, and Dr. ABRAHAMSON demonstrated lantern slides illustrating the gradual stretching of adhesions by pneumothorax.

REVIEWS AND NOTICES OF BOOKS

The Inborn Factors in Disease.

By Sir ARCHIBALD E. GARROD. Oxford: Clarendon Press. 1931. Pp. 160. 7s. 6d.

THERE are many good texts in this pregnant little book. And perhaps the best is Ryle's definition of a diathesis as "a transmissible variation in the structure or function of tissues rendering them peculiarly liable to react in a certain way to certain extrinsic stimuli." For it keeps clearly before our minds the essential consideration that a disease is a process in which the body is taking an active part and not merely a something by which it is possessed and injured. The extrinsic factors of disease—microbic, dietetic, œcological—have been hunted out these 50 years with such success that the inherent qualities of the organisms on which they impinge have been a good deal neglected, and we are grateful to Sir Archibald Garrod for reminding us, with all his graceful erudition, of many things which we ought to remember about the human constitution. And as we should expect from such a fruitful investigator, he is continually speaking as much of what is to be discovered as of what we know already. If, for example, we have such obvious congenital defects as alkaptonuria or hæmatoporphyrinuria, or such errors as cystinuria, which attracts attention by what is really the accident of a stone in the bladder, may there not well be other metabolic abnormalities, rare perhaps and not of vital import, which wait discovery? How much too there must be still to find out about the varying reactions of bodies which we can reasonably call normal to infections and the other changes and chances of social life.

Extrinsic hygiene is far from exhausted. But the rates of return are beginning to fall off, and no one with a liking for prophecy can doubt that personal constitution must inevitably come to play a larger and larger part in public health as well as in individual medicine. We know, for instance, that heritable qualities may be important factors in deciding whether a mouse develops a malignant tumour or how long a guinea-pig will survive inoculated tuberculosis. Sir Archibald Garrod's urbane philosophy forms an excellent background for the rigorous and difficult inquiries which are needed before we know how far the like applies to human populations. These are being pursued in various ways; to those to whom the dull and laborious task of accumulating human genetical data does not appeal, we commend Draper's method of exploring the association between particular diseases and the different types of bodily configuration.

Text-book of Ophthalmology.

Vol. I.: *The Development, Form, and Function of the Visual Apparatus.* By W. STEWART DUKE-ELDER, M.D., Ch.B., F.R.C.S. Eng., Surgeon, Royal London Ophthalmic (Moorfields) Hospital; Ophthalmic Surgeon to St. George's Hospital. London: Henry Kimpton. 1932. Pp. 1124. £3 3s.

MR. Duke-Elder has planned a text-book of ophthalmology on a monumental scale. The first volume deals solely with the anatomical, physiological, optical, and psychological foundations of the subject. A short opening section traces the genesis of the rudimentary eye beginning with the phototropism of the primitive organism. This is followed by a section on the anatomy of the human eye, its adnexa, and the central nervous mechanism of vision, in which are explained, not only the visual paths, the sensory, the sympathetic, and the oculomotor systems, but also the primitive connexion with the labyrinthine nerves and the postural centres in the mid-brain. A chapter on embryology comes next, and then others on the ocular pigment and on heredity. With the section on the physiology and biochemistry of the eyes the author comes to that part of his subject to which he has himself made original contributions, and the chapters on the vascular circulation and its control, on the metabolism of the eye, and on intra-ocular pressure may be considered the most authoritative part of the work. Chapters follow on the physiology of the pupil and of the extra-ocular

with deviation. This was entirely out of keeping with the idea of an advancing lower jaw. He had seen choanal obstruction without any malformation of the jaw. There was such a thing as adenoid facies, whatever its ætiology.

Dr. R. P. Garrow said that every education authority in the country was bound to have a scheme for the removal of tonsils and adenoids. The more he had seen of these operations the less he had liked them. He had seen no cases of nasal obstruction produced by adenoids. Child after child sitting open-mouthed in class could breathe through the nose without the least embarrassment when asked to do so. Any child who could not breathe through his nose had obstruction visible through the anterior nares.

Mr. Harold Chapman said that weight was not now regarded as necessary for Mr. Friel's lip-exerciser. A light aluminium rod and chain would prove cheaper and equally effective. A piece of cord through a sixpence would do quite well.

Mr. D. M. Shaw asked why "health talk" writers always advised their readers to inspire through the nose and expire through the mouth.

Mr. H. Kenshole asked whether or not dental irregularities were caused by breathing through the mouth, as had been taught.

REPLY.

Mr. Somerville Hastings said the action of the oral sphincters involved muscular work; they were not mere valves. He had known the whole shape of the jaw completely change after a couple of years with a closed mouth and proper negative pressure. He agreed that adenoids were often not present in the cases of open mouth (not necessarily used for breathing) associated with a peculiar shape of skull known as "adenoid facies." Adenoids might cause obstruction mechanically, but a far smaller mass of infected adenoid tissue, acting as a septic focus, might cause intermittent nasal obstruction by mucosal swelling.

Mr. Warwick said that he thought the arch was narrow because the tongue went back, and not vice versa. Suggestion was a very important factor in the use of the lip exerciser. Merely holding between the lips was insufficient; the child must be taught to put its tongue against its palate, swallow, and fix its mandible in the right position. Treatment should be started on the temporary dentition. The negative pressure was important in fixing the position of the mandible.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

A meeting of this section was held on April 15th, with Dr. H. F. Moore, the President, in the chair. Two cases of

Myasthenia Gravis

were shown by Dr. R. H. Micks. Both patients were women 26 years old, and the duration of the disease was 12 and 18 months respectively. The muscles first attacked in each case were those supplied from the medulla—the muscles of the face, the pharynx, and the sternomastoids being most affected. The arms, and to a lesser degree the legs, also showed weakness. In both cases the myopathy had already led to an unmistakable generalised muscular weakness which could be detected even when the patients were at their best and strongest, and there was also present the better-known and more dramatic characteristic of variability of the weakness. In one case the disease had apparently been stationary for the last six months. In the other there had been a few months ago an acute attack of dysphagia, dyspnœa, and cardiac weakness from which the patient had nearly died; she had now regained her status quo. Dr Micks demonstrated the chief clinical features of these cases and referred to the importance of recognising the presence of the gradual unvarying increase of muscular weakness.

The President spoke of the theory that in myasthenia gravis there is a disability of the carbohydrate metabolism of the muscles.—Dr. W. C MacFetridge said that these cases were of great importance to ophthalmic surgeons because the extrinsic muscles of the eye were particularly involved

Splenomegaly.

Dr. J. O'Connor showed a case of splenomegaly

The patient was a girl, aged 19, who was admitted to hospital in February complaining of swelling in the left side of the abdomen. She had first noticed it about two years before, but during the past year it had got much larger. At first it disappeared for a time, but then it came back, and she then experienced pain of a crampy nature, not very severe, in the left side. She had had amenorrhœa for the last two years. The kidneys were normal, and the cardiac and respiratory systems were both normal. A blood examination showed 6800 white cells per c.mm.; it was impossible to count the red cells owing to an extreme degree of auto-agglutination of the cells. A fragility test was normal. The hæmoglobin was 75 per cent. A Wassermann test done on two occasions was fully positive.

When he first saw the patient, Dr. O'Connor said he thought she had Banti's disease in the early stage No evidence of primary or secondary infection coul be obtained, and he regarded the case as one o congenital syphilis—with unusually late cirrhosis The patient was treated with novarsenobillon startin with 0·01 g. and after four injections she had a sever hæmatemesis, losing about a pint and a half of blood Treatment was discontinued for a few weeks, bu had now been resumed.

Dr. G. C. Dockeray said he thought it wa important to know whether this case was one of auto hæmagglutination or pseudo-agglutination.—Dr. A. F Parsons said he would be strongly against splenectomy in the present case.—Dr. Leonard Abrahamso referred to two cases of syphilis of the liver and splee One, a girl aged 16, had progressed favourably unde treatment; the condition was congenital. The othe a woman of middle age, developed thrombosis of t inferior vena cava and died. He suggested th Dr. O'Connor should consider the advisability splenectomy.

Dr. O'Connor said that he did not know whethe the condition was one of true agglutination or pseud agglutination. Statistics showed that in almo every case of Banti's disease in which there w evidence of sclerosis, splenectomy was followed by fatal result.

Prurigo-Asthma-Ichthyosis Complex.

Dr. E. T. Freeman, in reporting two cases, sa that in 1892, Besnier described a type of pruri which begins about the sixth month as an eczem affecting the cheeks and spreading down to the midd of the neck and to the limbs, where it eventually found most constantly at the flexures. The sk was thickened, covered with papules and lichenifi in these children, and was moist and oozing in f In recent years the combination of this type prurigo with asthma and ichthyosis had be cognised. It had been found that the earlier zema passes into the flexural prurigo, and that thma begins to be noted at about four or five years age. Ichthyosis to a greater or lesser degree was ways present. The skin condition tended to clear puberty, but the asthma remained. Most of the atients were sensitive to something—usually to iod proteins—and it was interesting to note that the rst signs appear about the time that foods other ian milk are added to the diet. Wheat was com- ionly a factor. Two cases under his care were the ollowing :—

> A girl, aged 14, had almost every conceivable treatment. he was put on a wheat- and egg-free diet, and was free from sthma for four weeks. On adding wheat and eggs the sthmatic attacks returned. She is now again free on the estricted diet.
>
> A boy, also aged 14, showed ichthyosis, patches of prurigo f the Besnier type, and a typical asthmatic chest with great ntero-posterior widening and indrawing of the lower ribs. Ie lived on a farm and was sensitive to cattle hair. In iospital he was free from attacks. He was also kept on a wheat-free diet.

These cases, said Dr. Freeman, were usually stated o have achlorhydria. One of these reported had, and the other had not. The basal metabolic rates were low.

Dr. Cyril Murphy mentioned a case of asthma in which the patient was sensitive to dog's hair. Her dog was given away and she remained free from asthma. Recently however she had come in contact with dogs, and the asthma had returned. He was now treating her with injections of dog's hair antigen and the result was very satisfactory. He thought that wherever the offending protein could be avoided, it was possible to bring about a cure of the disease.—Dr. W. G. Harvey referred to the use of auto-hæmotherapy in these cases, and said that he had found proteose injections useful in many conditions, but not in asthma.—Dr. Abrahamson laid stress on the importance of a careful history. Without it the skin tests were often confusing and misleading.

Dr. Freeman in replying said that it was almost impossible to cure asthma in elderly people, or in cases which arose from infection in the lungs. The only cases in which it was possible to obtain really good results were young people, and cases in which the offending protein could be eliminated. He had found auto-hæmotherapy of use in cases of pruritus, but not in asthma.

Dr. O'Connor read a note on Some Cases of Artificial Pneumothorax, and Dr. Abrahamson demonstrated lantern slides illustrating the gradual stretching of adhesions by pneumothorax.

REVIEWS AND NOTICES OF BOOKS

The Inborn Factors in Disease.

By Sir Archibald E. Garrod. Oxford : Clarendon Press. 1931. Pp. 160. 7s. 6d.

There are many good texts in this pregnant little book. And perhaps the best is Ryle's definition of a diathesis as "a transmissible variation in the structure or function of tissues rendering them peculiarly liable to react in a certain way to certain extrinsic stimuli." For it keeps clearly before our minds the essential consideration that a disease is a process in which the body is taking an active part and not merely a something by which it is possessed and injured. The extrinsic factors of disease—microbic, dietetic, œcological—have been hunted out these 50 years with such success that the inherent qualities of the organisms on which they impinge have been a good deal neglected, and we are grateful to Sir Archibald Garrod for reminding us, with all his graceful erudition, of many things which we ought to remember about the human constitution. And as we should expect from such a fruitful investigator, he is continually speaking as much of what is to be discovered as of what we know already. If, for example, we have such obvious congenital defects as alkaptonuria or hæmatoporphyrinuria, or such errors as cystinuria, which attracts attention by what is really the accident of a stone in the bladder, may there not well be other metabolic abnormalities, rare perhaps and not of vital import, which wait discovery? How much too there must be still to find out about the varying reactions of bodies which we can reasonably call normal to infections and the other changes and chances of social life.

Extrinsic hygiene is far from exhausted. But the rates of return are beginning to fall off, and no one with a liking for prophecy can doubt that personal constitution must inevitably come to play a larger and larger part in public health as well as in individual medicine. We know, for instance, that heritable qualities may be important factors in deciding whether a mouse develops a malignant tumour or how long a guinea-pig will survive inoculated tuberculosis. Sir Archibald Garrod's urbane philosophy forms an excellent background for the rigorous and difficult inquiries which are needed before we know how far the like applies to human populations. These are being pursued in various ways ; to those to whom the dull and laborious task of accumulating human genetical data does not appeal, we commend Draper's method of exploring the association between particular diseases and the different types of bodily configuration.

Text-book of Ophthalmology.

Vol. I. : *The Development, Form, and Function of the Visual Apparatus.* By W. Stewart Duke-Elder, M.D., Ch.B., F.R.C.S. Eng., Surgeon, Royal London Ophthalmic (Moorfields) Hospital ; Ophthalmic Surgeon to St. George's Hospital. London : Henry Kimpton. 1932. Pp. 1124. £3 3s.

Mr. Duke-Elder has planned a text-book of ophthalmology on a monumental scale. The first volume deals solely with the anatomical, physiological, optical, and psychological foundations of the subject. A short opening section traces the genesis of the rudimentary eye beginning with the phototropism of the primitive organism. In one case the disease had apparently been stationary for the last six months. In the other there had been a few months ago an acute attack of dysphagia, dyspnœa, and cardiac weakness from which the patient had nearly died; she had now regained her status quo. Dr. Micks demonstrated the chief clinical features of these cases and referred to the importance of recognising the presence of the gradual unvarying increase of muscular weakness.

The PRESIDENT spoke of the theory that in myasthenia gravis there is a disability of the carbohydrate metabolism of the muscles.—Dr. W. C. MACFETRIDGE said that these cases were of great importance to ophthalmic surgeons because the extrinsic muscles of the eye were particularly involved.

Splenomegaly.

Dr. J. O'CONNOR showed a case of splenomegaly.

The patient was a girl, aged 19, who was admitted to hospital in February complaining of swelling in the left side of the abdomen. She had first noticed it about two years before, but during the past year it had got much larger. At first it disappeared for a time, but then it came back, and she then experienced pain of a crampy nature, not very severe, in the left side. She had had amenorrhœa for the last two years. The kidneys were normal, and the cardiac and respiratory systems were both normal. A blood examination showed 6800 white cells per c.mm.; it was impossible to count the red cells owing to an extreme degree of auto-agglutination of the cells. A fragility test was normal. The hæmoglobin was 75 per cent. A Wassermann test done on two occasions was fully positive.

When he first saw the patient, Dr. O'Connor said, he thought she had Banti's disease in the early stage. No evidence of primary or secondary infection could be obtained, and he regarded the case as one of congenital syphilis—with unusually late cirrhosis. The patient was treated with novarsenobillon starting with 0·01 g. and after four injections she had a severe hæmatemesis, losing about a pint and a half of blood. Treatment was discontinued for a few weeks, but had now been resumed.

Dr. G. C. DOCKERAY said he thought it was important to know whether this case was one of auto-hæmagglutination or pseudo-agglutination.—Dr. A. R. PARSONS said he would be strongly against splenectomy in the present case.—Dr. LEONARD ABRAHAMSON referred to two cases of syphilis of the liver and spleen. One, a girl aged 16, had progressed favourably under treatment; the condition was congenital. The other a woman of middle age, developed thrombosis of th inferior vena cava and died. He suggested tha Dr. O'Connor should consider the advisability o splenectomy.

Dr. O'CONNOR said that he did not know whethe the condition was one of true agglutination or pseudo agglutination. Statistics showed that in almos every case of Banti's disease in which there wa evidence of sclerosis, splenectomy was followed by fatal result.

Prurigo-Asthma-Ichthyosis Complex.

Dr. E. T. FREEMAN, in reporting two cases, sai that in 1892, Besnier described a type of prurig which begins about the sixth month as an eczema affecting the cheeks and spreading down to the midd of the neck and to the limbs, where it eventually found most constantly at the flexures. The ski was thickened, covered with papules and lichenif in these children, and was moist and oozing in fa In recent years the combination of this type prurigo with asthma and ichthyosis had recognised. It had been found that the earlier eczema passes into the flexural prurigo, and that asthma begins to be noted at about four or five years of age. Ichthyosis to a greater or lesser degree was always present. The skin condition tended to clear at puberty, but the asthma remained. Most of the patients were sensitive to something—usually to food proteins—and it was interesting to note that the first signs appear about the time that foods other than milk are added to the diet. Wheat was commonly a factor. Two cases under his care were the following :—

A girl, aged 14, had almost every conceivable treatment. She was put on a wheat- and egg-free diet, and was free from asthma for four weeks. On adding wheat and eggs the asthmatic attacks returned. She is now again free on the restricted diet.

A boy, also aged 14, showed ichthyosis, patches of prurigo of the Besnier type, and a typical asthmatic chest with great antero-posterior widening and indrawing of the lower ribs. He lived on a farm and was sensitive to cattle hair. In hospital he was free from attacks. He was also kept on a wheat-free diet.

These cases, said Dr. Freeman, were usually stated to have achlorhydria. One of these reported had, and the other had not. The basal metabolic rates were low.

Dr. CYRIL MURPHY mentioned a case of asthma in which the patient was sensitive to dog's hair. Her dog was given away and she remained free from asthma. Recently however she had come in contact with dogs, and the asthma had returned. He was now treating her with injections of dog's hair antigen and the result was very satisfactory. He thought that wherever the offending protein could be avoided, it was possible to bring about a cure of the disease.—Dr. W. G. HARVEY referred to the use of auto-hæmotherapy in these cases, and said that he had found proteose injections useful in many conditions, but not in asthma.—Dr. ABRAHAMSON laid stress on the importance of a careful history. Without it the skin tests were often confusing and misleading.

Dr. FREEMAN in replying said that it was almost impossible to cure asthma in elderly people, or in cases which arose from infection in the lungs. The only cases in which it was possible to obtain really good results were young people, and cases in which the offending protein could be eliminated. He had found auto-hæmotherapy of use in cases of pruritus, but not in asthma.

Dr. O'CONNOR read a note on Some Cases of Artificial Pneumothorax, and Dr. ABRAHAMSON demonstrated lantern slides illustrating the gradual stretching of adhesions by pneumothorax.

REVIEWS AND NOTICES OF BOOKS

The Inborn Factors in Disease.

By Sir ARCHIBALD E. GARROD. Oxford: Clarendon Press. 1931. Pp. 160. 7*s.* 6*d.*

THERE are many good texts in this pregnant little book. And perhaps the best is Ryle's definition of a diathesis as "a transmissible variation in the structure or function of tissues rendering them peculiarly liable to react in a certain way to certain extrinsic stimuli." For it keeps clearly before our minds the essential consideration that a disease is a process in which the body is taking an active part and not merely a something by which it is possessed and injured. The extrinsic factors of disease—microbic, dietetic, œcological—have been hunted out these 50 years with such success that the inherent qualities of the organisms on which they impinge have been a good deal neglected, and we are grateful to Sir Archibald Garrod for reminding us, with all his graceful erudition, of many things which we ought to remember about the human constitution. And as we should expect from such a fruitful investigator, he is continually speaking as much of what is to be discovered as of what we know already. If, for example, we have such obvious congenital defects as alkaptonuria or hæmatoporphyrinuria, or such errors as cystinuria, which attracts attention by what is really the accident of a stone in the bladder, may there not well be other metabolic abnormalities, rare perhaps and not of vital import, which wait discovery? How much too there must be still to find out about the varying reactions of bodies which we can reasonably call normal to infections and the other changes and chances of social life.

Extrinsic hygiene is far from exhausted. But the rates of return are beginning to fall off, and no one with a liking for prophecy can doubt that personal constitution must inevitably come to play a larger and larger part in public health as well as in individual medicine. We know, for instance, that heritable qualities may be important factors in deciding whether a mouse develops a malignant tumour or how long a guinea-pig will survive inoculated tuberculosis. Sir Archibald Garrod's urbane philosophy forms an excellent background for the rigorous and difficult inquiries which are needed before we know how far the like applies to human populations. These are being pursued in various ways; to those to whom the dull and laborious task of accumulating human genetical data does not appeal, we commend Draper's method of exploring the association between particular diseases and the different types of bodily configuration.

Text-book of Ophthalmology.

Vol. I.: *The Development, Form, and Function of the Visual Apparatus.* By W. STEWART DUKE-ELDER, M.D., Ch.B., F.R.C.S. Eng., Surgeon, Royal London Ophthalmic (Moorfields) Hospital; Ophthalmic Surgeon to St. George's Hospital. London: Henry Kimpton. 1932. Pp. 1124. £3 3*s.*

MR. Duke-Elder has planned a text-book of ophthalmology on a monumental scale. The first volume deals solely with the anatomical, physiological, optical, and psychological foundations of the subject. A short opening section traces the genesis of the rudimentary eye beginning with the phototropism of the primitive organism. This is followed by a section on the anatomy of the human eye, its adnexa, and the central nervous mechanism of vision, in which are explained, not only the visual paths, the sensory, the sympathetic, and the oculomotor systems, but also the primitive connexion with the labyrinthine nerves and the postural centres in the mid-brain. A chapter on embryology comes next, and then others on the ocular pigment and on heredity. With the section on the physiology and biochemistry of the eyes the author comes to that part of his subject to which he has himself made original contributions, and the chapters on the vascular circulation and its control, on the metabolism of the eye, and on intra-ocular pressure may be considered the most authoritative part of the work. Chapters follow on the physiology of the pupil and of the extra-ocular

muscles. We do not find the author's account of the anatomy and the physiology of the ciliary muscle altogether satisfactory. The term "scleral spur" occurs several times but to understand what it is, its connexion with the longitudinal fibres of the ciliary muscle on the one hand and with Schlemm's canal on the other, we have to turn to the original description by Prof. Arthur Thomson, of Oxford (*Ophthalmoscope*, 1911, ix., 470). It is a pity that the figures accompanying this original article were not reproduced, for nowhere else have we met such a clear explanation of the action of the longitudinal fibres of the ciliary muscle in opening up Schlemm's canal.

The action of the ciliary muscle in accommodation presents difficulties and is not fully explained by Mr. Duke-Elder. While agreeing that Helmholtz's theory in its original form needs modification, he fails to show how the different portions of the ciliary muscle coöperate with each other in causing relaxation of the zonule. Mr. Thomson Henderson, of Nottingham, believes that the only fibres which are directly concerned in positive accommodation are the circular fibres, the longitudinal fibres, which he calls "sustentaculum zonulæ," and the radiating fibres, which he calls "tensor zonulæ," being concerned in maintaining the zonular curve while accommodation is relaxed. According to this view these two latter sets of fibres are antagonistic to the first and their positive action is called into play not in accommodating for a near object, but in fixing a distant one. It would have been interesting to have this view either criticised or confirmed. After a section which includes chapters on optics—physical, geometrical, and physiological—we come to parts of the subject which are still somewhat obscure. These include the action of visible light on the retinal cells, colour vision, adaptation and after images, and the duplicity theory of vision—that rods and cones are adapted respectively for vision in twilight and daylight. This theory Mr. Duke-Elder now regards as established, though some authorities, notably Dr. Edridge Green, still oppose it. The last chapter deals with visual perceptions and especially with binocular vision.

This work is not an introduction to the study of ophthalmology. The student who should attempt to use it in this way would soon get lost in a maze of technicalities which would take him considerable time to master and this process would postpone unnecessarily his contact with actual clinical problems. It is rather a book of reference for the use of those who already have considerable knowledge of the subject, and contains copious references to authorities on each section of ophthalmology. This volume contains over 1000 illustrations, including seven coloured plates. We look forward to the publication of its fellows, for the work when complete will be a rich contribution to the literature on normal and abnormal conditions of the eye.

Life: Outlines of General Biology.

By Sir J. ARTHUR THOMSON and PATRICK GEDDES. London: Williams and Norgate, Ltd. 1931. Two Vols. Pp. 1515, with 202 figures. 63*s*.

Geddes and Thomson on "The Evolution of Sex" was published in 1889—forty-two years ago. It was a famous book which led to much productive work and thought. Since then they have both been fully active in their respective spheres—Thomson mainly as a biological zoologist, Geddes as a botanist and social reformer. They come together again now in the ripeness of their knowledge and experience and have produced an extraordinary compendium in which they survey the whole field of biological knowledge and speculation with a comprehensive success that one would have thought hardly possible. They deal in turn with the essential characteristics of organisms, with their relation to environment, with physiology, reproduction, behaviour, organic architecture, development, evolution, human biology, and the general theory of life. To any one reader, some parts will naturally seem better than others; to the present reviewer the chapters on evolution appeal as particularly excellent. The easy fluency of Thomson will suit most people better than Geddes's craggy sentences and strange formulæ. But if some parts are better than others, there are no parts which are bad, and if anyone wants to have a serious knowledge of where biology stands to-day we advise him to get the book and spend some weeks or months in reading it right through. Detailed criticism of such a book is obviously impossible but we may note these points about the general outlook of the authors; they believe in evolution, past, present, and future, as the most fundamental fact about live organisms; they are vitalists and hold that mind is an integral part of life; they believe that human life in all its aspects is a proper subject of biological study, however far a cry it may seem from chromosomes to civics.

Diet and Pleasure.

The Art of Enjoying Medical Régimes. By PAUL REBOUX. London: G. P. Putnam's Sons Ltd. 1932. Pp. 248. 6*s*.

THIS small book has the unusual merit of presenting sound and valuable information under the guise of amusing chit-chat; the anecdotes and illustrations are often quite funny, while the general regimens laid down are sound, and the culinary instructions accurate and sometimes elaborate enough to have proceeded from Alexis Soyer—who may have been occasionally the source of inspiration. The plan of the book is extremely simple: some dozen conditions, not so much diseases in themselves as symptoms common to many diseases, have been chosen for discussion, and general information as to the causation is supplied in justification of a series of menus suitable to the patient's needs. Many of these menus call for very expert cooking and the ingredients included in some of them cannot always be readily come by, but the fare provided would be charming. For the help of housewives the author has collected together in lists at the end of the book a series of menus for the week suitable to each of the maladies dealt with. Some of the items would considerably try any cook who wished to produce them.

CITY OF LONDON MATERNITY HOSPITAL.—In 1931 the number of mothers admitted was 1759, an increase of 110; of the 1673 delivered 7 died, or 3·82 per 1000. The patients stayed on an average 14·60 days, and cost £8 6*s*. 2*d*. each—a small decrease. The income was £16,486, and there was left a credit balance of £56.

THE AFFAIRS OF STAMFORD INFIRMARY.—We recorded last week (p. 914) that the Marquess of Exeter, president and chairman of Stamford and Rutland Infirmary, and other governors, had resigned in consequence of a threat that an annual grant of £300 would be withdrawn unless Dr. G. Staveley-Parker, who had been dismissed from the honorary staff, was reinstated. The reinstatement took place, and since then 15 governors, including the president, have resigned. At a meeting of the governors last week a vote of confidence in Lord Exeter was passed unanimously, and a committee of five members was appointed "to investigate and report on the conduct of Dr. Staveley-Parker towards the Infirmary."

MEDICAMENTA VERA P.D. & Co.

The Product of Unique Experience

PARKE, DAVIS & Co. introduced Adrenalin to the medical profession in 1901. During the thirty years that have elapsed, they have manufactured it continuously, and their long experience has convinced them that natural Adrenalin possesses many advantages over the synthetic product.

Adrenalin (P., D. & Co.)—the original and well-tried preparation—is extracted from the medullary portion of selected adrenal glands. The isolated substance is then standardised by both physiological and chemical methods to secure full activity of the finished preparations.

Medical men can make sure of obtaining an Adrenalin that is potent, uniform in action, and reliable by specifying "P., D. & Co.".

Full particulars of Adrenalin (P., D. & Co.) and its uses in medicine will be supplied on request. Adrenalin Chloride Solution, P., D. & Co., is supplied in bottles and ampoules. Hypodermic Tablets, Inhalant, Lozenges, Suppositories, Ointments, etc., and Adrephine (Adrenalin - Ephedrine Compound) are also available.

ECONOMIC ASPECT OF THE RHEUMATIC DISEASES.

It is, in a sense, unfortunate that the death-rate from chronic rheumatism should be insignificant; were this not so it can be accepted as certain that more attention would long since have been directed to the solution of the many problems connected with this protean disease. The social importance of the rheumatic group of diseases is to-day greater than that of the two more successful claimants to official attention—tuberculosis and cancer. Adult rheumatism is in fact probably the greatest single factor in the production of industrial invalidity and in the depletion of national health insurance funds. Sir WALTER KINNEAR has estimated the cost to the country of this group of diseases as little short of seventeen million pounds a year. While our knowledge of their ætiology and treatment falls very short of what might be desired, it should not be forgotten that considerable stores of knowledge have been accumulated in recent years, and could be made available in the event of any renaissance of interest in the subject. The field is vast; much of the soil is still virgin and presents a legitimate field for specialisation.

The first organised outlet for much of this knowledge, for discussion of the main problems confronting us, and for constructive planning for the future was provided earlier in the year by the Royal Institute of Public Health. This body, recognising the serious social menace of the rheumatic group of diseases to be a subject which could properly and profitably be approached from the public health aspect, organised a series of weekly lectures on "Rheumatism and arthritis as a public health problem," which may be taken as a sign of the awakening of a more progressive attitude towards the problem, and of promising augury for the future. Sir WILLIAM WILLCOX in the opening lecture, while granting the existence of doubt in the origin even of cases properly recognised as of infective nature, expressed his conviction that these diseases are largely preventable and in the earliest stages curable. Dr. FORTESCUE FOX traced the rise of public interest in chronic rheumatism from the early nineteenth century, when the five great spa hospitals were solitary voices of hope crying in a medical wilderness, up to the time of the establishment in London of the British Red Cross Society's experimental clinic at Peto-place three years ago. The care of all diseases of social importance had, he said, in the past gradually been forced by public opinion to become the responsibility of competent bodies. With the recognition by the medical profession of the value of physical methods at some period in almost every rheumatic case, the need for properly organised study and attack was seen, and the establishment of physical treatment centres in industrial areas as part of a comprehensive scheme should follow. Dr. D. M. CONNAN, medical officer of health for the Borough of Bermondsey, which is proposing to deal with arthritis on these lines, pointed to signs that certain municipal and insurance bodies are determined in the near future to see that these methods of treatment are available for the insured population. It would, he thought, be disastrous for the medical profession to find, when their interest was awakened, that others had been before them. Dr. M. B. RAY attributed the lack of progress in our study of the origins of rheumatic disease to reliance on the shibboleth of focal sepsis and to neglect of such factors as endocrine imbalance, exhaustion, heredity, and occupational stress. Dr. A. R. NELIGAN, as the result of prolonged study of methods in other countries, showed how the more concentrated effort abroad is based on a belief that the results repay the cost of the subsidies granted. In the final lecture, of which an abstract appears on p. 967, Dr. W. S. C. COPEMAN outlined a scheme for an organised campaign against rheumatism in this country.

For financial reasons Dr. COPEMAN believes it necessary to segregate diagnosis and investigation in special centres, and to centralise all treatment. But the basis of any such scheme must, as he very reasonably points out, be the insurance practitioner. At the present time when faced with a case of arthritis, whether in the potentially curable or in the advanced stage, his scope is limited by the provisions of the National Health Insurance Acts which provide general practitioner service and nothing more for the insured population. Additional benefits have however been sanctioned for the use of approved societies able to show a surplus on the quinquennial valuation, and four years ago, following on Dr. ALISON GLOVER's report,[1] physical medicine was placed on the list of these additional benefits. Coming sixteenth on the list as it does its application must remain restricted to members of the wealthiest societies. Moreover it is idle to advocate the employment by the insurance practitioner of methods which find no place in the regular teaching of medical schools. If these methods are to become available on a large scale for the insured population, some way must be found whereby treatment can be administered under skilled direction and according to the proper indications in centralised clinics. The success of such clinics, if forthcoming, is assured by the example of the Peto-place clinic, which was the outcome of the demand made by approved societies for the provision of skilled investigation and treatment for their members. Its foundation was the dawn of a new era for the arthritic. In the United States it has been recognised, since Dr. R. W. LOVETT introduced what has been called the Vermont plan, that the management of the arthritic requires a minimum of hospital care and a maximum of after-care. In Massachusetts there is a movement afoot to provide for the 145,000 arthritics in the State a system by which instruction and care is given in the homes after patients have been seen in the clinic.[2] The total amount of crippling, it is believed, has already been reduced by effort of this kind.

IRON REQUIREMENTS IN NUTRITION.

GREAT interest has for many years been shown by students of nutrition in the methods by which iron is obtained by the organism for the purpose of elaborating hæmoglobin. Two problems in particular have engaged their attention—namely, the amount of iron that should be regularly supplied and the chemical form in which it should be presented to ensure adequate utilisation. It may be remembered that for many years the question was debated whether simple inorganic salts or more complicated organic compounds were the normal source of iron. Modern investigations have shown repeatedly that simple iron salts can be effectively utilised, although it seems equally clear that organically bound iron is a satisfactory source and indeed probably forms the greater part of the necessary supply of the average individual. The only available test of the adequacy of the iron supply for a given individual at present is his capacity for maintenance of a normal concentration of hæmoglobin or for producing regeneration of hæmoglobin when this has been reduced from any cause below the normal level; and we are now coming to realise that this capacity depends on other factors besides the quantity of iron supplied and the chemical form in which it is exhibited—for instance the simultaneous supply of copper and possibly other mineral elements. Such facts as these have emerged from studies of nutritional anæmia, a condition experimentally produced in young animals by exclusive diets of milk which has long been known to be relatively deficient in iron.

It is true that some doubts have been cast from time to time on the assumption that milk is necessarily deficient in iron, and not long ago SCOTT and ERF[3] claimed to have shown that young rats could be successfully reared with normal concentrations of hæmoglobin if they were fed exclusively on raw milk from selected cows which were given special diets containing a salt mixture which included iron and copper. Such results, if substantiated, would not invalidate the results of previous experiments on nutritional anæmia and we may therefore consider it proved that the quantitative iron requirements of an individual are not fixed and unalterable, but are liable to vary with the supply of other elements in the diet. This consideration must tend to complicate the problem of the normal minimum iron requirement. Some approximation to this quantity may be obtained by measuring the intake and output of iron by healthy individuals on a good mixed diet which is not likely to be deficient in any known food constitutents, and measurements of this kind have indicated that 10 mg. a day is the average requirement for an adult. For young children it has been calculated that about 0·5 mg. a day should be allowed per kilo of body-weight. If such calculations have a practical interest it is important that the iron content of common foods should be known, and many series of chemical analyses have been published in recent years which deal with this point. A recent report on the iron content of vegetables and fruits has been published in America.[4] The list of articles examined is comprehensive and the results are summarised by classifying them as poor, fair, good, and excellent sources of iron, the criteria being respectively iron contents of less than 0·0004 per cent., between 0·0004 and 0·00079 per cent., between 0·0008 and 0·00159 per cent., and more than 0·0016 per cent. The last group contains kale, parsley, peas, spinach, turnip tops, and water-cress; the first contains apples, pears, peaches, pineapples, and melons. Most of the vegetables eaten in this country are entered under the "fair" or "good" headings and it is interesting to find potatoes classed as a good source of iron. These results confirm the accepted view that vegetables, and particularly leafy vegetables can be an important source of iron in mixed diets.

A SURVEY OF HOSPITAL PRACTICE.

SINCE their origin in mediæval days as refuges for the sick poor, in alliance, loose or close, with the Crown and the Church, the hospitals in this country have undergone a wide expansion of function; and now that their activities have come to include the treatment of those who are not destitute but who can afford to pay a fee, sometimes equalling or even exceeding their cost of maintenance, we have a fundamental change in their position towards society. The January issue of *Nosokomeion*, in a survey of the scope of hospitals in various countries, shows that this expansion of hospital service is not confined to England alone, and in a series of closely written articles sets out the hospital systems in a number of European countries, and in Turkey, the United States, Australia, and Canada. In France the position resembles that found in England; even before the war, hospitals were opening their doors to middle-class patients wishing to make use of the equipment and skilled treatment available there. The hospitals here, moreover, are becoming more and more centres of preventive and sanitary medicine, and there is increasing collaboration between them and the public health services of the country. Attached, for example, to the hospitals of the Assistance Publique are centres for vaccination against small-pox, diphtheria, and tuberculosis—by B C G; antenatal and infant welfare clinics, obstetric and venereal disease clinics, and centres for the study of cancer; mental hygiene and orthopædic clinics are also included, as well as a social welfare service. In Italy, apparently, the hospital service is considerably less comprehensive; indigent patients are visited in their homes by the municipal medical officer and midwife, and are only removed to hospital in an emergency or for surgical treatment.

[4] Stiebling, H. K.: 1932, United States Dept. of Agriculture, Circular No. 205.

In Germany and Austria, concurrently with a rapid increase in the provision of hospital beds, the scope of hospital service has been enlarged and regularised. Better coördination between the different bodies engaged in preventive or curative medicine has been achieved by the establishment of health services, and of commissions composed of representatives of the public bodies, insurance societies and private organisations, while the hospital clinics carry their work into the realm of social welfare. Australia shows a system differing in several respects from those which have grown up in European countries, and the situation represents well how the rise and growth of institutional medicine must be closely related to the social history of the population. Australian colonisation was carried out by groups of hardy and intelligent people, none of whom fell into the European definition of sick poor. As soon as a small settlement became large enough to support it, a hospital of some kind was set up to serve the sick persons of the community as a whole. These hospitals developed under central Government subsidy and local control, and although the public health system proceeded independently, it was kept in close correlation with the institutions. The administration of the health departments varies in different localities, but in all of them the hospitals cover the range of necessary services for the care of the sick and maintain a large out-patient service. In Canada the development of the hospital system has not been unlike that of Australia, a trail of hospitals following the colonists as they settled. In prairie districts union hospitals have been established, under the combined control of a number of municipalities, taxpayers being admitted at reduced rates. Most of the larger hospitals maintain their own social service departments. There is, however, no system of compulsory or voluntary health insurance, and most of the cost is borne by the patient at a time when he can least afford it. Hospitals are maintained by the fees of private patients supplemented by provincial and municipal grants. In Turkey the troubled transformation from Eastern to Western manners finds its portrait in the hospital position. The provision of hospitals is still quite inadequate for the needs of the population, but their number is showing a steady increase. There is as yet no general administration for public welfare, and the hospitals are subsidised by the various Government departments to which they are attached. There are also in Turkey a certain number of voluntary hospitals; some are due to foreign intervention and are obtaining their support in accordance with the pattern of the countries of their origin. This is interesting, and the growth of a voluntary hospital movement in Turkey might well be watched when the existing position of these institutions in other countries is becoming increasingly difficult, the supply of private subscribers being so seriously threatened.

Of the hospitals of the United States no fair survey can possibly be made in anything like a summary form; the populations are huge, and the different States, though not comparable upon cultural grounds, hold strongly to their autonomy. But everywhere the hospitals are open to all the population, and the well-to-do obtain accommodation at rates presumably adjusted to their means. Naturally this is a source of legitimate anxiety to doctors who are not on the hospital staffs and who suffer from hospital competition, but for reasons already implied there is no general hospital policy in the country, and but little coöperation between public, voluntary, and private institutions. If in the United States such want of order affects a greater number of people, and over a vastly greater geographical range, we can still see in this country a somewhat similar state of affairs. This it was which led to the late Dr. **PARLANE KINLOCH**'s activities on his appointment as chief medical officer for Scotland. He reorganised and strengthened the medical department, and brought the public to appreciate problems of public health and the difficulties in which medical men were too often placed in the task of administration. He secured the establishment of a committee to develop and advise on medical investigations in Scotland, and to relate fundamental work in science to the administration of the health services. The work that he initiated in Scotland had at his untimely death already begun to attract international notice, and such a survey as that supplied by *Nosokomeion* shows how applicable that work was to present day needs.

ARMY ADVISORY COMMITTEE ON MAXILLO-FACIAL INJURIES.

THE War Office announces the formation of a standing advisory committee under the Director-General, A.M.S., in order to investigate and report on the treatment of maxillo-facial injuries. Colonel J. P. Helliwell, A.M.S., Assistant Director-General for Dental Services, will be the chairman of the committee, and Major S. H. Woods (Army Dental Corps), its secretary. Mr. W. Kelsey Fry has been appointed by the British Dental Association, and the other members at present appointed are Sir Harold Gillies and Mr. W. Warwick James. The committee will make recommendations for the provision of special facilities and equipment for these cases, the general methods of treatment, and the training of dental officers in the principles of preliminary treatment in the field.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS, GLASGOW.—Mr. R. Barclay Ness, the president, took the chair at the Finlayson lecture delivered in the hall of the Faculty on April 21st. The lecturer, Sir D'Arcy Power, took as his subject the Progress of Surgery in a London Hospital, 1880–1930. A vote of thanks was proposed by Prof. T. K. Munro.

it has been recognised, since Dr. R. W. LOVETT introduced what has been called the Vermont plan, that the management of the arthritic requires a minimum of hospital care and a maximum of after-care. In Massachusetts there is a movement afoot to provide for the 145,000 arthritics in the State a system by which instruction and care is given in the homes after patients have been seen in the clinic.[2] The total amount of crippling, it is believed, has already been reduced by effort of this kind.

The January issue of *Nosokomeion*,[1] in a survey of the scope of hospitals in various countries, shows that this expansion of hospital service is not confined to England alone, and in a series of closely written articles sets out the hospital systems in a number of European countries, and in Turkey, the United States, Australia, and Canada. In France the position resembles that found in England; even before the war, hospitals were opening their doors to middle-class patients wishing to make use of the equipment and skilled treatment available there. The hospitals here, moreover, are becoming more and more centres of preventive and sanitary medicine, and there is increasing collaboration between them and the public health services of the country. Attached, for example, to the hospitals of the Assistance Publique are centres for and Wells concludes that the strain was one of those which in addition to the power of producing a necrotising toxin also possessed a high degree of "invasiveness." He urges the need for more careful study of all intradermal virulence tests of suspected diphtheria cultures showing local reactions in both protected and unprotected guinea-pigs before calling them negative especially in routine work with field cultures. Although its importance is obvious the observation of Wells is not new. Okell and Parish found that the intraperitoneal injection of antitoxin did not sufficiently protect against some strains, the control animal showing definite local lesions. Owing to similar experiences W. Mair[3,4] has given up the use of the control animal when testing pure cultures as unnecessary and indeed as misleading "if it is not remembered that rare strains of virulent *C. diphtheriæ* occur with which even very large doses of antitoxin do not prevent cutaneous lesions." Allison also finds the use of the control animal unnecessary when working with pure cultures. If field cultures are being tested a control animal is essential.

PUERPERAL SEPSIS IN GLASGOW.

THE Puerperal Pyrexia Regulations, and administrative measures following their enforcement, have made for greater use of hospital facilities and for notification: nevertheless, Dr. A. S. M. Macgregor, addressing the Section of Epidemiology of the Royal Society of Medicine on April 22nd, showed that the maternal mortality-rate from puerperal sepsis in Glasgow has not diminished. Certification in Glasgow, he admitted, had been much more accurate in recent years; in the past, cases had sometimes been certified as pneumonia or septicæmia without any reference to childbirth, and increasing frankness probably had some effect in maintaining the returns at a high level. More patients, however, are treated in hospital, 93 per cent. of those notified in Glasgow being admitted to fever hospitals or the isolation blocks of maternity homes, and the case-mortality is falling. Delay in admission to hospital does not seem to be responsible for the high death-rate, since 62 per cent. of 200 fatal cases investigated were admitted within three days of the onset of symptoms. Cases with infection reaching the blood-stream form the most fatal group in the Glasgow investigation, and Dr. Macgregor suggests that streptococcal infections may be exceptionally virulent in Glasgow and the north country. Using antiscarlatinal serum there was sustained improvement in a few cases, but in many no change was noted. Serum has, however, given promising results when used prophylactically in cases with severe lacerations. Dr. Macgregor laid special stress on the reduction of the chances of infection; the forceps rate in the series of 200 fatal cases was 24 per cent., and trauma was present in some 40 per cent. of cases. The first interim report of the departmental committee on maternal mortality indicated strongly that improved obstetric practice would reduce the mortality to some extent, but if a more virulent streptococcus is prevalent in the north, the solution is still to seek; in the nature of things the rigid asepsis of a surgical operation can never be achieved in midwifery, and chances of infection must always exist. Dr. Remington Hobbs, in the discussion which followed, spoke of the value of glycerin irrigation, while other speakers dealt with administrative difficulties. Dr. Clark Trotter, medical officer of health for Islington, said he had had his returns questioned by the London County Council on the grounds that he was making out a much worse case for his borough than other boroughs were able to do. This was because the deaths connected with childbirth were notified as such, and not merely under the head of the terminal condition. Dr. D. Sage Sutherland spoke of the admirable administrative measures in Manchester, to which he attributed the low mortality-rate from puerperal fever in that city. He mentioned the good results of intravenous treatment with arsenical drugs combined with glycerin-iodine irrigation of the uterus, and gave it as his impression that, if the traumatic factor could be eliminated from midwifery, hospital treatment would be effective in dealing with any cases of sepsis which might arise, and in reducing the mortality to small proportions. It was remarkable throughout the discussion how little emphasis was laid on carrier infection. Dr. Macgregor admitted that he fought shy of it because it would increase administrative difficulties so greatly if it should prove to have any marked influence, but he also expressed doubt of its importance.

BOTHRIOCEPHALUS ANÆMIA.

Albrecht in 1883 was probably the first to call attention to the association of helminthiasis and pernicious anæmia. J. W. Birkeland,[1] who has reviewed subsequent work on infestation with *Diphyllobothrium latum,* concludes that the anæmia is almost always of the pernicious type and indistinguishable from the idiopathic form except in small points. Leucopenia is less conspicuous, and immature white cells are to be seen. Achlorhydria is found in only some 80 per cent. of cases, and the acid may return after discharge of the worm. Organic nervous involvement is extremely rare, while glossitis and stomatitis are common even in those cases without anæmia. The causal relationship of the worm to the anæmia has long been discussed. There appears to be a strong racial predisposition: 391 of 508 reported cases come from Finland, and of those occurring in America 21 were Finnish emigrants. Japan, Italy, and Rumania, though heavily infected, have reported only four cases. Even in Finland, however, anæmia results in only 0·1–0·5 per cent. of affected persons, which suggests that apart from a racial element there is a further personal predisposing factor. In 15 cases the anæmia has been noted in two or more members of the same family, and in four cases it has accompanied "idiopathic" pernicious anæmia in some other member of the family. Further, there are 17 cases in which many years after expulsion of the worm idiopathic pernicious anæmia has developed. The latter might be considered coincidence; the preponderance of anæmia in Finns must, however, have some significance, while the dramatic hæmatological and clinical improvement following expulsion of the worm is further proof of a definite causal relationship. G. Becker,[2] who studied the effect of liver treatment in a large series of cases, found it was almost always successful, and was followed by a typical reticulocyte response. The same response was seen after expulsion of the worm when no liver was given, and in these cases the cure was permanent, whereas if the worm was still present liver treatment had to be continued indefinitely. The quantity or quality of the worm or the duration of infestation appears to be without significance. There is no satisfactory evidence that the worm secretes toxins

ANNOTATIONS

SPEECH AND INTELLIGENCE.

THERE is probably no better index of subnormality of intelligence than marked retardation in the first appearance of speech and, following upon that, its unusually prolonged development. There are a few children of normal intelligence who show some degree of delay in speech acquirement. There are also certain "freak" cases who may be almost dumb up to a certain stage and then begin to speak with surprising fluency. There are also, of course, the children born deaf who are necessarily dumb; but, putting all these aside, there can be no doubt that an undue delay of speech is, as a rule, a stigma of mental defect. It is a more reliable indicator of mental subnormality than the frequently parallel lateness of development in teething and walking, which may be due to other causes, such as rickets. A paper in this issue by Dr. A. G. Morison provides an interesting study of the speech phenomena manifested by a group of defectives educable and ineducable in respect of lateness of development, indistinctness of articulation, lalling, echolalia, use of words, and idioglossia. The figures he gives clearly show a relation between relative retardation of speech and intelligence, none of the educable cases having started to speak later than 5 years, while 18 out of 34 ineducables did not begin to speak until after 5, 7 of them even over 9 years of age. The persistence of lalling for periods of 5 to 6 years after the commencement of speech in a group of high-grade cases is also worthy of note. It is a mark of the mental inertia which, even more than lack of intelligence, is the distinguishing mark of many defectives. Morison's most surprising observation, however, is the correlation between the results of intelligence tests and a vocabulary test, which appear to agree with the results of Terman, who was responsible for the Stanford revision which Morison used. One would have expected a vocabulary test to be very largely affected by the home environment of the child, and certainly all observers have not obtained similar results.

The whole paper forms a useful corrective to the tendency among parents and sometimes amongst practitioners to a too cheerful prognosis in cases of late and imperfect speech. There are a certain number of children who make no effort to talk because their wants are supplied by assiduous attendants, and this form of laziness is compatible with plenty of intelligence. But in general the normal child should be speaking a few words at one year, and should articulate clearly between three and four. Where these figures are much exceeded, a somewhat guarded prognosis regarding ultimate mental development is necessary.

AN ANTIDOTE FOR AVERTIN?

FROM previous work in connexion with pregnancy Dr. Adolph Bolliger[1] was led to believe that thiosulphate was used in the process of detoxication in pregnancy. He therefore sought to demonstrate the detoxicating properties of the substance in a more standardised intoxication produced experimentally. For this purpose he employed avertin, and the results he achieved may well prove of some importance in the clinical use of this anæsthetic. Dogs were given the minimal lethal dose of avertin. Sodium thiosulphate was administered intravenously, subcutaneously, or rectally either before, with, or after the avertin injection. The group of experiments demonstrated that in the laboratory at least avertin anæsthesia can be controlled by adding varying amounts of sodium thiosulphate to the avertin solution. Simultaneous rectal administration of avertin and hypertonic sodium thiosulphate delays the absorption of the avertin to such an extent that with a 30 per cent. solution of the thiosulphate anæsthesia cannot be obtained. Bolliger states that the delayed and diminished absorption of avertin in the presence of sodium thiosulphate probably represents a special case of a general law, that when two crystalloids are given rectally each may influence the absorption of the other in proportion to their respective amounts present. This delaying action might be useful in obstetrics. In cases of overdose he found that high rectal irrigation with warm hypertonic sodium thiosulphate solution acted as a restorative if applied before cardiac failure took place. This may have a practical bearing, since at present we have no definite antidote for an overdose of avertin. Thyroxin takes so long to act as to be rarely of use clinically.

VIRULENT STRAINS OF DIPHTHERIA.

ALTHOUGH, as V. D. Allison[1] reports, it is possible, by using a special medium, to recognise many avirulent strains of *Corynebacterium diphtheriæ* by cultural characteristics alone, the most reliable method of differentiating between virulent and avirulent strains of the organism is the test in vivo. The intradermal method is that most usually employed. As a rule, two guinea-pigs for test and control respectively are used. The bellies of both are carefully epilated in the way described by C. C. Okell and H. J. Parish (1926). Following the technique of Eagleton and Baxter (1921), the control animal receives intraperitoneally a protecting dose of antitoxin the night before, whilst the test animal is injected by the same route with a "following dose" four or five hours after inoculation. W. Mair[2] prefers to give the test animal antitoxin subcutaneously immediately after inoculation. The inoculum may consist of a suspension of a field or mixed culture or preferably of a pure culture of the strain to be tested. For comparison, a suspension of a pure culture of known virulence is also inoculated. Virulence of the strain is indicated by the occurrence upon the skin of the test animal of a rose-red swelling which ultimately becomes necrotic. The skin of the control animal shows nothing or a faint transient flush (Eagleton and Baxter). Any lesion upon the skin of the control animal is regarded as due not to toxin but to some other cause. The appearance of lesions upon both animals would thus be liable to be read as a negative result and the strain recorded as avirulent.

J. R. Wells[3] has lately drawn attention to a complication of the intradermal method. When testing a number of recently isolated pure cultures it was found that one culture produced severe necrosis at the site of inoculation in both test and control animals. The latter had been protected two hours previously by intraperitoneal injection of 400 units of diphtheria antitoxin. Subsequent investigation of the culture in question ruled out the possibility of contamination

year—and this rate of wastage will soon lessen since about half of all the doctors are now under 40, compared with 28 per cent. in 1920. Some 30 to 40 years ago there was also a wave of congestion in the medical profession in Norway, but then the United States was willing to absorb the surplus. This is no longer so; the Norwegian doctors now practising in the U.S.A. belong exclusively to the older generation. It should be added that the population of Norway in 1930 was 2,810,800.

DEAD SPACE.

THE epidemiological importance attributed to the presence of dead space in dormitories and class-rooms in a discussion reported on another page should be noted by those who are concerned with the conversion of buildings, erected for other purposes, to serve as schools or hospitals. Dead space may be defined as that space in a room which is above the level of the window openings. A moderate amount, say one foot in height in a small room or two in a very large room, is probably of little importance, but a large space of three or four feet or more in height above the level of the window openings has dangers unsuspected by the casual visitor who may be inclined to praise a high "airy" room. Warm polluted air which rises to fill a dead space accumulates undisturbed, cools, and falls again. carrying with it infected particles which should have been removed by ventilation. Definite evidence of the harmful effect of such dead space is not easy to obtain, but experienced observers are developing a strong prejudice against the adaptation of palaces, hotels, and country houses as residential institutions. The condition is difficult and expensive to remedy, needing a structural change or the provision of much extra window space. It is not always easy to detect patches of stagnant air, though tests with smoke, ammonium chloride evaporated over a lamp, titanium chloride, or smouldering phosphorus can be used effectively. There is, of course, considerable atmospheric turbulence in any room. The technique of making smoke rings would not be so difficult to acquire if the air were really still, but even if small eddies and movements are present, macroscopic stagnation may occur in the upper strata which are largely unaffected by open windows. The free use of a katathermometer or a sensitive form of anemometer in different parts of a very high room might help to indicate stagnation, which could be remedied by special devices. But though one of the speakers at the discussion was inclined to believe that lofty dormitories are advantageous, most epidemiologists now hold that large dormitories as well as large hospital wards should not be more than 12 feet or less than 11 feet high, and that in smaller dormitories a height of 10 feet is sufficient. Air changes should be effected by the introduction of fresh air and the removal of heated breathed air and not by diffusion or convection into a dead space used as a reserve.

NATIONAL RADIUM CENTRES IN THE PROVINCES.

A MEMORANDUM (Circular 1276) from the Ministry of Health draws the attention of county and county borough councils to the facilities available through the establishment of eight national radium centres in provincial voluntary hospitals in England and Wales. The centres are the Royal Infirmaries at Bristol, Liverpool, Manchester, Newcastle-upon-Tyne, Sheffield, and Cardiff. the Birmingham General Hospital, and the General Infirmary, Leeds, and the Radium Commission has in mind the establishment of a number of smaller regional centres, chiefly to meet the needs of the East Anglian and south-western districts. The hospitals concerned undertake certain obligations, designed to ensure that the radium is used to best advantage and that full records of cases, including follow up, are kept. They are pledged to accept and to treat suitable and properly accredited patients from any source, including such as come from rate-aided institutions. Local authorities are urged to make arrangements to secure for the inhabitants of their area the fullest benefit from the facilities provided by the centres.

VETERANS.

ON April 30th, the date of our present issue, Dr. James Gairdner. of Crieff. will have been a registered medical practitioner for 65 years. But others have been registered longer. A survey of the 55,604 names in the Medical Register, 1932, shows that Dr. Jacob Dickson Hunter, of Arequipa, Peru, registered on Dec. 31st, 1858; Dr. James Middleton. of Stow, Midlothian, on March 20th, 1861; Sir James Crichton Browne. on July 5th. 1862; Dr. William Goldie Stevens, of Renfrew, on Oct. 19th. 1863; and Dr. James Carmichael, of Edinburgh, on Jan. 11th, 1866. All were registered in Scotland.

MICROSCOPY OF VIRUSES.

THOSE who took part in the discussion on April 20th at the Royal Microscopical Society on the microscopy of filtrable viruses fell into two quite definite groups. There were the microscopists whose main concern was the technique of the microscopy of minute particles—a not unreasonable attitude considering the subject and setting of the discussion; and the pathologists who were interested in microscopy only in so far as it formed one of the various methods necessary to the study and identification of viruses. This difference in attitude gave the impression, quite an erroneous one, that the pathologists were indifferent to the niceties of microscopical technique, and that for the microscopists the study of filtrable viruses could be summed up in one word—microscopy. In opening the discussion Mr. A. E. Barnard referred to the radical change in attitude to the problem of the nature of filtrable viruses which had taken place in the last three years. As the majority of workers in this country now accept the view that these agents are minute micro-organisms, the major problem confronting workers is to establish the nature of the minute bodies whose presence, in the case of some filtrable viruses at any rate, has been known of for so long. In this task Mr. Barnard would give pride of place to the examination of these bodies, unstained and in the living state, by means of dark-ground condensers with ultra-violet light; most convincing was the demonstration he gave of the superiority of the technique which he has evolved over the conventional method of examining stained preparations by visual light. That does not mean that the latter method is without value for, as Dr. S. P. Bedson pointed out, the minute bodies in psittacosis material. whose discovery was the work of staining methods alone. had been shown to be the virus, and the same could be said of the Paschen bodies and Borrel bodies of vaccinia and fowl-pox respectively. Nor is technique proof against erroneous conclusions.

or hæmolysins, or that the blood of carriers contains antisubstances. Birkeland believes that the rôle of the worm is only that of a precipitating factor or trigger mechanism. It is possible that it acts by destroying the effective principle necessary for hæmopoiesis normally produced in the stomach, and that when this is administered in large quantities in the form of liver, there is enough for both parasite and host. Systematic anthelmintic measures have reduced the mortality from nearly 100 per cent. to 12 per cent. Further interesting evidence as to the part played by the worm might be obtained by use of the ingenious technique used by H. S. Wells in the investigation of hookworm anæmia described in an annotation last week (p. 893). That the mechanism is essentially different is suggested by the fact that hookworm anæmia is hypochromic in character and is relieved by iron.

CYTOCHROME.

PARTICULAR interest centres around the pigments on which the processes of life depend. The outstanding properties of hæmoglobin and of chlorophyll have long been known, although there is reason to suspect that they are not fully known even now; but it was only in 1925 that Prof. D. Keilin described to the Royal Society a yellow pigment with a respiratory function, common to animals, yeasts, and some of the higher plants, which he called cytochrome. Recent work on this pigment by Dr. C. B. Coulter and Dr. Florence Stone, of Columbia University, has established the fact that cytochrome belongs to the porphyrin group of pigments which includes both hæmoglobin and chlorophyll; but whereas in the blood the porphyrins are combined with iron, in the leaves of plants they are combined with magnesium, while according to the work done at Columbia they are combined with iron and copper to make up cytochrome. In contrast with chlorophyll, by means of which starch is built up from the carbon dioxide present in the air, cytochrome serves the opposite purpose of breaking down carbohydrates. Dr. Coulter has been investigating the occurrence of cytochrome in various malignant tumours, finding it present in some and absent in others. He has also noted that the amount of this pigment set free in the development of diphtheria cultures is strictly proportional to the amount of toxin formed, and in this observation lies the brilliant possibility of being able to estimate the amount of toxin without resort to biological test. A small amount of cytochrome is present in tuberculin. A short notice of this new work appeared in the *New York Times* of April 5th, and the publication of full details will be awaited with interest.

HORSESHOE KIDNEY.

A PAPER by Howard S. Jeck[1] deals fully with the precautions to be taken in the operative treatment of horseshoe kidney. In the records of autopsies at the Bellevue Hospital, New York, he finds that the condition is present once in every 643 cases—a greater incidence than is usually given. The average age at death—excluding cases in infants under one year of age—was 43 years, which supports the view that the span of life of these patients is below the normal. In all the 26 cases discovered the fusion of the kidneys was by an isthmus connecting the lower poles, and in one of them there appeared to be only one ureter. With the steadily increasing use of urography the pre-operative diagnosis is becoming more and more common; since 1918 four of these cases have been operated upon at the Bellevue Hospital, in two of which a pre-operative diagnosis was made. Of the other two one was operated upon in 1918 when urography was not so frequently carried out, and in the other a complete examination could not be made owing to the poor condition of the patient. Jeck enumerates the points to be noted in diagnosis by means of a urogram, and then makes mention of the break which is found in the continuity of the psoas outline shadow, a feature which was described as recently as last year at the meeting of the American Urological Association. The pre-operative diagnosis is obviously of great help to the surgeon, and adds to the ease and safety of the operation. If a heminephrectomy is contemplated the operator must be satisfied as to the function of the remaining half of the kidney—that it has its own ureter and adequate blood-supply. The division of the isthmus calls for care. If of the fibrous type it can be divided between clamps, and then a whipover stitch is used on the side of the remaining segment; if, however, it is composed of parenchyma the difficulties are greater, the isthmus may be divided by a knife or cautery, and a wedge-shaped type of incision is to be recommended so that the lips of the incision can be opposed. It is also to be remembered that a calyx may extend into the isthmus, and if so it must be avoided or a urinary fistula may result. In the discussion which followed the reading of Dr. Jeck's paper at the annual meeting of the American Medical Association, Dr. R. Gutierrez referred to what he called the horseshoe kidney syndrome characterised by epigastric or umbilical pain radiating to the lumbar region, chronic constipation, and urinary disturbances. Dr. W. E. Stevens reported an interesting case in which a third pelvis and ureter arose from the isthmus.

CONGESTION IN THE MEDICAL PROFESSION IN NORWAY.

FIGURES compiled by Dr. H. Blich Holst[1] reveal a state of affairs very serious for the younger members of the medical profession in Norway. At the beginning of 1932 there were 1888 persons qualified to practise medicine in Norway, where in 1925 the corresponding figure was only 1504. In 1930 the number of medical students had risen to 1540; in other words, the medical students in this year outnumbered all the fully qualified doctors in the land in 1925. At the beginning of 1932 there were 795 medical students who had got so far as to pass their preliminary medical examinations, and were thus qualified to begin clinical work in the hospitals. But the accommodation in the two teaching hospitals in Oslo allows for the absorption of only 50 students each term. The students at the end of this formidable queue would, accordingly, have to wait eight years before they could resume their medical studies. In 1931 a new crop of 172 students entered for the course of medical studies. Dr. Holst exclaims in this connexion: "What on earth are these poor fellows thinking of?" He finds the prospects more than sad for the coming generation. Even if every other man falls out of the queue in the coming eight years, there will still be some 400 who will emerge as doctors during the next few years, and there is not room for them all. The normal annual wastage for several years has been under 2 per cent.—i.e., under 40 a

SPECIAL ARTICLES

MEDICINE AND THE LAW.

Sale of Herbal Remedies: a Prosecution.

NEARLY 400 years ago Parliament passed an Act to protect "divers honest persons, as well men as women, whom God hath endued with the knowledge of the nature, kind and operation of certain herbs, roots and waters." The Act declared that these persons were taking nothing for their pains or cunning but had ministered to poor people "only for neighbourhood and God's sake out of pity and charity"; yet they were being sued, troubled, and vexed by the Company and Fellowship of Surgeons of London who were making the most of a recent statute which restricted the practice of physic and surgery to persons approved and admitted by prescribed authority. Parliament consequently enacted that for the future everybody having this knowledge and experience of herbs, roots, and waters either by speculation or by practice may use his skill in ministering to "any outward sore, uncome, wound, apostemations, outward swelling or disease" any "herbs, ointments, baths, pultes and emplaisters" without being sued, vexed, or troubled by the Company of Surgeons.

This old Act (33 and 34 Henry VIII., ch. 8) still stands upon the statute book unrepealed. The herbalists may cite it as their charter, though anyone who, owing to his ignorance of the properties and scientific application of dangerous drugs, administers an improper dose, may be found criminally liable. Such restrictions upon herbalists' remedies as modern law contains are mostly provisions enacted in the interests of the revenue. Under these the Society of Herbalists, Ltd., was fined at Westminster police-court on April 19th, upon a series of charges under three heads. First it was complained by the Commissioners of Customs and Excise that the defendant Society was selling medicines without complying with the stamp duty, though warned last July that the law was being ignored. Secondly, the Society was charged with selling on unlicensed premises; it had always had a licence in respect of its Baker-street premises but it had none for its other establishments. The licence fee is only 5s., but here again the law was being ignored. Thirdly, the Society was charged with selling a herbal mixture for smoking, contrary to Section 8 of the Tobacco Act, 1842, which forbids anyone to "cut, grind, pound, colour, stain, dye, or manufacture any leaves or any herb, or plant, moss or weed, or any wood, chicory, commings or roots of malt or any other vegetable or other matter or materials to imitate or resemble tobacco or snuff." It is an offence under this section to prepare any such materials for mixture with tobacco or snuff, or to have them in possession for this purpose.

The penalties under these various provisions are substantial. The magistrate did not find that the Society had made any deliberate attempt to evade payment of duties, but he thought there had been great carelessness. He inflicted a series of fines which, with costs, amounted to £147 11s. The proceedings under the Tobacco Act were dismissed without conviction on payment of £5 5s. costs. Possibly the magistrate thought this ninety-year-old statute an indifferent engine of the law. Our legislation about the sale of medicines, indeed, might also well be modernised.

Septicæmia and Accident Insurance.

Many fatal cases of septicæmia are the sequelæ of an accident. The King's Bench Division has had to consider whether a fatal case of septicæmia, apparently originating from a pimple at the junction of the nostril and lip, could properly be described as a death due to accident. The deceased had insured himself at Lloyd's under a policy entitling his legal representatives to about £83,000 if (within the period covered) his death should be directly due to bodily injury by accident. The policy expressly stipulated that it was not to cover either death directly or indirectly caused or contributed to by disease or natural causes, or death directly or indirectly resulting from medical or surgical treatment. The widow and executors, in claiming under the policy, had therefore to show that the death was due to accident. The deceased had died while on a trip round the world in a liner with his wife and a friend. The friend had endeavoured to help him by squeezing the pimple. The underwriters, resisting the claim, argued that death was due to natural causes; they did not need, it seems, to rely on the argument that the amateur assistance given by the friend amounted to "medical or surgical treatment" within the wording of the policy.

The evidence of the ship's doctor, taken on commission, was read at the trial; but it threw little light on the origin of the septicæmia. The friend who had treated the pimple described what had occurred. The deceased seems to have been subject to boils and pimples which had been similarly treated before. On this particular occasion, it was said, a probe was used, but no pus was brought away in the squeezing. The plaintiffs relied on this fact as establishing an accident causing death, because the pus, they said, was driven inwards and the infection, up to that time superficial, entered the deeper tissues with fatal consequences. Mr. Justice Roche was unable to see that the treatment, if applied as described, had the effect suggested. It was doubtful, he said, whether the friend's treatment did any mischief; he found himself unable to see that what was done could have caused injury. The plaintiffs had failed to establish that there was any accident or accidental injury giving rise to the *furuncle*. There was no evidence that the pimple was due to an insect bite; Sir Bernard Spilsbury's evidence had shown that it was probably due to acne lesions which are the result of natural disease and natural infection. The fact that death was caused by "bodily injury by accident" was not proved; judgment was therefore given for the defendants with costs.

Private Cars and Conveyance of "Goods or Burden."

A curious situation has arisen under the law relating to the taxation of motor vehicles. Vehicles "constructed or adapted for use and used for the conveyance of goods or burden of any description, whether in the course of trade or otherwise," pay mechanically propelled vehicles duty at a higher rate than ordinary private motor-cars. The revenue is protected by clauses which inter alia impose a fine if a vehicle is unlawfully used for a purpose to which a higher rate of duty applies. Under this provision a greengrocer and florist was fined at Cardiff for using a 16 h.p. motor-car of the ordinary saloon type to carry vegetables, fruit, and flowers.

Prof. J. C. G. Ledingham instanced the organism of bovine pleuro-pneumonia which, on the strength of ultra-violet microscopy, had been credited with a life cycle consisting of spherical forms which multiplied by budding, whereas his own investigations of this organism in stained preparations led him to the conclusion that it had fungal affinities and that the filtrable phase consisted of minute spores which were developed in conidia. There can be no doubt however that Mr. Barnard has supplied virus workers with a method of investigation of which the value will be increasingly apparent as more workers adopt the technique; as far as obtaining virtual images of these minute organisms it stands alone.

NEPHROSTOMY.

Prof. Hugh Cabot is paying one of his now too rare visits to this country and spreading a trail of stimulating ideas in his wake. His remarks at a meeting of the Urological Section of the Royal Society of Medicine, a report of which will appear in THE LANCET next week, should do much to revive the interest of British urologists in a useful method of restoring the function of badly damaged kidneys, and of saving many that would otherwise have to be removed. Prof. Cabot makes no claim to have introduced a new method of treatment. As long ago as the end of last century nephrostomy was advocated by Henry Morris in this country in cases of obstructed and hydronephrotic kidneys. But though this operation may have been performed frequently in the past, recent writings on urological subjects give little indication that it is in common use at the present time, and it would be ungracious to pretend that British urologists need no reminder of its value. It is often more difficult to rehabilitate an old method than to produce a new one, and genito-urinary surgeons will be grateful to Prof. Cabot for his attempt to revive drainage of the kidney as a potent means of restoring function, even when there appears to be no function left to restore. Prof. Cabot used the term nephrostomy in its strict sense to mean drainage through the kidney, whether temporary or permanent, as opposed to pyelostomy, a drainage through the pelvis, and nephrotomy or pyelotomy to mean incision only without drainage. He discussed its use in various renal conditions such as calculous disease, hydronephrosis, and chronic infections, and pointed out that drainage through the renal substance has the effect of restoring renal function rapidly. The cases of restored function that he quoted were most encouraging; they had obviously been very thoroughly examined and tested for renal function by all the usual methods, and Prof. Cabot was able to state that many kidneys which showed no function at all would recover as much as half the functional capacity of a normal kidney after drainage. He made no exaggerated claims for nephrostomy, and indeed erred on the side of modesty in stating his case in favour of conservative renal surgery in place of nephrectomy for apparently functionless kidneys. His work may well form the starting point of a new interest in the subject among urologists in this country.

THE NOMENCLATURE OF DISEASES.

THE classical volume, revised every 10 years by a joint committee appointed by the Royal College of Physicians, on the Nomenclature of Diseases, has now reached its sixth edition.[1] Though it is dated 1931 it has only just been issued, at a price (5s.) to those not on the free list which is more than double that of the fifth edition published in 1918. Few will grudge the extra charge in view of the better production of the volume, now in the convenient royal octavo format which is being adopted for most official publications in this country. Eighty of these larger pages are now devoted to the diseases of the various systems of the body, against 158 in the former edition, the space having been saved mainly through the use of double columns and the more advantageous use of white space between subsections instead of between each name. Appendices include Tumours and Cysts, Malformations, Parasites and Vectors of Disease, Poisons, and an illuminating list of additions and alterations. Among the additions we notice abortus fever, hookworm disease, tularæmia; many rare neurological conditions; air-sickness, mountain sickness, serum sickness; paraphrenia and schizophrenia; thrombophlebitis migrans; asbestosis and massive collapse of the lung; acidosis, alkalosis, ketosis; deficiency diseases; embolic focal nephritis, glomerulo-tubular nephritis, nephrosis, lipoid and toxic, and toxæmic kidney. These terms among many others indicate conditions less generally recognised or at least less clearly defined in 1918, and provide an encouraging reminder of the progress made in the last 10 years. On the other hand, at least one term, status thymo-lymphaticus, has been allowed to survive when the condition it represents is no longer recognised as a pathological entity. The doubt expressed in a memorandum by the subcommittee on classification, whether the sections of the Appendix dealing respectively with parasites and vectors of disease and with poisons should be excluded, has happily been resolved, for this edition at least, in favour of their retention. We trust that their usefulness will be so cordially proclaimed that they will find a place in future editions. A searching examination of the index has revealed neither error nor the slightest ambiguity. This is an admirable production which reflects credit on the distinguished men who have been honoured by an invitation to help in its compilation, and especially on Dr. Cecil Bosanquet who has ably fulfilled the task of secretary and editor.

MEDICAL RESEARCH FELLOWSHIPS.—The Rockefeller Medical Fellowships and the Dorothy Temple Cross Research Fellowships in Tuberculosis for the academic year 1932–33 will shortly be awarded by the Medical Research Council. The value of these Fellowships will be not less than £350, exclusive of allowances.

Fellowships are awarded by the Council, in accordance with the desire of the Rockefeller Foundation, to graduates who have had some training in research work in the primary sciences of medicine, or in clinical medicine or surgery, and are likely to profit by a period of work at a university or other chosen centre in the United States before taking up positions for higher teaching or research in the British Isles. In special circumstances the Fellowships may be tenable at centres of research not in America.

The object of the Fellowships in tuberculosis is to give special opportunities for study and research to persons "intending to devote themselves to the advancement by teaching or research of curative or preventive treatment of tuberculosis in all or any of its forms." Candidates must be British subjects and must possess suitable medical, veterinary, or scientific qualifications. It may be possible to award a Senior Fellowship of considerably greater value to a specially well-qualified candidate.

Further particulars are obtainable from the Secretary, Medical Research Council, 38, Old Queen-street, Westminster, London, S.W. 1, with whom applications must be lodged before June 1st.

[1] H.M. Stationery Office. 1931. Pp. 220. 5s.

light instead of by transillumination. It is admitted that the photographic detail is inferior to that of the celluloid films. However, in a series of 100 cases controlled by independent records and readings on celluloid films no significant lesions were missed through the use of the paper film. Two hundred and fifty films may be exposed and developed in a single roll. By the use of a special viewing device the developed films are read seriatim between two rollers. The cost by this method is only one-third the cost of separate celluloid films. The new roll films are being used also by the Queensboro Tuberculosis Association in a project which requires the X ray examination of 40,000 school-children in the next four years.

NEGRO HEALTH WEEK.

We have just concluded the national Negro Health Week. This is an outgrowth of the "Health Improvement Week" proposed by the late Booker T. Washington in 1915. Washington was the founder of the famous Tuskegee Institute and held that "the future of the negro race depends on the conservation of its health." In 1929 the negro death-rate was 17 per 1000 in contrast to the rate of 11 per 1000 for white Americans. The expectancy of life is ten years less for negro than for white. The Health Week by promoting interest in public health measures seeks to lessen these discrepancies.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

SOME REMARKABLE INFANT WELFARE STATISTICS.

IN a communication to the Academy of Medicine on March 1st Dr. Mourier presented a report on the mortality among infants coming under the care of the public authorities in the Seine area. Before 1921 this mortality ranged from 30 to 40 per cent. It was 36 per cent. in 1920. In 1921 each infant welfare centre was provided with one or more visiting nurses who formed a permanent link between the persons in charge of these infants and the doctor, and who filled in the gaps between his visits at intervals of ten days. Largely in response to this reform the infant mortality fell in 1922 to 16 per cent. It remained about this figure during the next four years. In 1927 the Antony Creche, an annexe to the Hospice-Dépositaire, was linked up to the infant welfare centres in the provinces in such a way that this creche became the centre for the distribution of sterilised cow's milk. Boiled before despatch to the infant welfare centres, this milk has become the babies' sole food since the almost complete disappearance of the wet nurse. This reform was followed by another remarkable fall in the infant mortality, which in 1928 reached 9·42 per cent. In 1931 the figure was down to 5·95 per cent. These results are the more impressive when it is realised that the material under review included the many infants received by the public authorities in a sickly and debilitated state. Statistics including children up to the age of 18 months told the same tale. In this group the mortality fell from 15 per cent. in 1924 to 4·4 per cent. in 1931. The infant mortality from gastro-enteritis has shown a corresponding decline; among an annual roll of about 1200 infants, there were 71 deaths from this cause in 1924, as compared with 7 in 1931. The machinery which has made this wonderful achievement possible deserves study by all interested in infant welfare.

PREPARATIONS FOR CHEMICAL WARFARE.

France in general, and Paris in particular, is thinking this year more than ever in terms of aerial and gas warfare. For more than four years a mixed commission of all the authorities concerned has held meetings at the headquarters of the three national Red Cross societies. The French Red Cross does not confine itself to training nurses for first-aid duties in connexion with gas attacks; it also provides teachers in this field for the boy scouts and girl guides. Another body, the "Association nationale des veuves d'officiers," is organising feminine teams to give first-aid to civilians in case of aerial bombardment. There are already four instruction centres in full activity, one at the prefecture of police, one at the headquarters of the Red Cross, one at the Pasteur Institute, and one at the Musée Social. Throughout March courses in the theory of the subject were given, and they were followed in April by practical training. Several thousand persons have already joined these courses, full attendance on which is followed by the receipt of a certificate and the privilege for the holder thereof to become enrolled, if she so wishes, in the groups put at the service of the authorities for combating aerial and gas warfare. As Madame Rodillon, president of the "Association nationale des veuves d'officiers," has recently stated, it is desirable that in every family there should be one woman qualified to give first-aid and to neutralise the effects of a sudden gas attack. Some idea of the intensity of the work of preparation now going on in Paris against aerial and gas warfare is given by the statement, recently made by the head of the police, that "the work is constant, for it is necessary every day to introduce modifications into the arrangements made."

THE SERVICES

ROYAL ARMY MEDICAL CORPS.

Lt. J. Crealey resigns his commn.

H. T. Chiswell is granted a temp. commn. in the rank of Lt.

ARMY DENTAL CORPS.

The undermentioned Lts. to be Capts.: W. A. McClelland and W. B. Martin.

ROYAL MALTA ARTILLERY.

Surg. Maj. R. Randon retires on retd. pay.

R. L. S. C. G. Casolani to be Surg. Lt.

TERRITORIAL ARMY.

Lt.-Col. C. V. Bulstrode resigns his commn, and retains his rank with permission to wear the prescribed uniform.

Maj. H. Mather resigns his commn. and retains his rank with permission to wear the prescribed uniform.

Capt. J. Broadfoot, having attained the age limit, retires and retains his rank with permission to wear the prescribed uniform.

Capt. P. J. Stokes, from T.A. Res of Off. (R.A.M.C.), to be Capt.

J. G. McDowell to be Lt.

ROYAL AIR FORCE.

Group Capt. H. W. Scott is placed on the retd. list on account of ill-health.

OPHTHALMIC HOSPITALS.—Last year 76 beds, including 14 in the private rooms, were kept in full use at the Royal Westminster Ophthalmic Hospital. There were 1195 in-patients (150 private), and 11,225 new out-patients. The growing requirements of the hospital increased the expenditure by £2000. The school of ophthalmology was well attended.—In 1931 Belfast Ophthalmic Hospital treated 9742 cases, of which 3713 were ear, nose, and throat cases. The expenditure was £1821, a reduction of over £100, and there was a small credit balance. Most of the patients paid a little towards the cost of treatment, and there was a large increase in subscriptions.

The car had two seats for passengers; it was not "constructed or adapted for use" or in any way altered so as to convey goods; but it was in fact being "used for the conveyance of goods or burden." The Cardiff stipendiary magistrate convicted the owner of the car, and the King's Bench Division (Mr. Justice Macnaghten dissenting) has upheld the conviction. The result is that a motorist carrying his own luggage or a surgeon carrying his instruments may technically be guilty of an offence; conversely the owner of a high-powered motor-car may, by claiming to be conveying goods or burden by virtue of fitting a luggage carrier, show some ground for being taxed at a lower rate. The police presumably will exercise discretion in instituting prosecutions while the law remains in this condition. The embarrassment of the situation was not allowed to affect the majority decision last week. The result, observed Mr. Justice Avory, may be far-reaching and may produce what the ordinary public will call an absurdity; but all that this Court has to do is to construe the statute.

A Spiritualist's Libel Action.

The libel action brought against the *Daily Mail* by Mrs. Meurig Morris ended in a verdict which seemed to embody a compromise. Mrs. Morris complained of a contents bill which said "Trance Medium Found Out" and of comments which suggested that her spiritualistic experiences were fraudulent. The defendants pleaded justification and fair comment on a matter of public interest. The verdict was a finding for the defendants on the plea of fair comment, but the jury added that they did not consider that the allegations of fraud or dishonesty had been proved. Mr. Justice McCardie thereupon gave judgment for the defendants but allowed Mrs. Morris to set off against the general costs of the action the costs to which she had been put by the defendants' unsuccessful plea of justification.

Medical evidence, offered in proof of Mrs. Morris's sincerity, described her going into a trance. Before she did so, she was sensitive to the slightest pin-prick; her pulse was 86 and her temperature was normal. She then passed her hands across her face and became pale; her eyes closed; her left hand and the left side of her face became colder than the right; she was insensitive to pin-pricks, and her pulse went up to 130. In the trance state she rose from her chair, spoke in a man's bass voice, seemed to acquire a dominating personality, and held her dress where the lapels of a man's coat would be. Mrs. Morris herself gave evidence of the controls or discarnate spirits which spoke through her. On two occasions during the trial she manifested strong emotion in a dramatic manner. Once, while in the witness-box, she declared that she saw a vision of Christ standing close to her. During the judge's summing-up, she rose, seized the lapels of her coat and said in a deep voice "Thou, who art a brother judge, hearken unto my voice." On each of these occasions Mr. Justice McCardie adjourned the court for a short period until Mrs. Morris recovered her normal calm and the proceedings could continue in a less emotional atmosphere.

Sir Oliver Lodge and other witnesses testified to the plaintiff's honesty; she did not use her gifts to make money. The defendants, on the other hand, while unsuccessful in producing any proof of fraud, attributed to her the power of simulation and pretence; they said that the sermons which she purported to preach contained nothing new; they commented on the happy punctuality with which "Power" and the other controls appeared when required at public meetings; they hinted that something like rehearsals had been overheard before these public performances. Between these two widely different views the trial, long as it was, has not helped the public to decide. Those who already believed in spiritualism and the revelations of mediums will believe in them still. Those who disbelieved will not have been converted. Comparatively little use seems to have been made of the opportunity to inform the court of the symptoms and conditions of hysteria.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

PUBLIC HEALTH REFORM IN NEW YORK STATE.

THE final report of the Special Health Commission of New York State[1] has now been published with a long foreword by Governor Franklin D. Roosevelt. As favourite candidate for the presidential nomination on the Democratic ticket the attitude of Governor Roosevelt to public health is of national interest. In a newspaper interview given on April 6th Governor Roosevelt is even more frank than in his foreword. Our present town and village system of local health administration is, he says, as wasteful of lives as of money. Only the indifference of local government can explain the continuance of diphtheria in some municipalities after it has been stamped out in others. The recommendations of the Commission are described as "a broadly conceived, long range plan . . . practical and easy to follow." Governor Roosevelt then announced that on April 22nd he would call a conference of health leaders to discuss the immediate steps to be taken towards establishment of the new health programme. He concludes: "The expert technical knowledge, the administrative experience in public health, and the sound judgment of the Commission members which has found expression in this report, will, I hope, be translated promptly into law and transmitted by practice into the lives of the people."

THE PAPER ROLL FILM.

The economics of roentgenography are becoming of urgent importance to American physicians. It is agreed that we must be able to diagnose tuberculosis in its childhood stage, and that for this purpose the symptoms and signs upon which our fathers relied are of little account. Most cases in childhood will not even show malnutrition, the family history is regarded as being of small importance, and even the tuberculin test is of limited value. The one and only measure which gives satisfactory insight to the modern clinician is the X ray. But routine X ray examination of thousands of school-children (and literally thousands are concerned, even though the examination be limited to tuberculin-positive cases) becomes a matter of such great expense that even the richer communities of the Eastern states hesitate to avail themselves of the new method. Fluoroscopy has economic advantages, but is unsatisfactory by not revealing sufficient detail. At the Bellevue-Yorkville health centre in New York Dr. Margaret Barnard has been experimenting with paper roll film. The developed paper film which she has used gives an opaque positive which is read by direct

---

Decree of December, 1930, exempted from this requirement all persons incapacitated for more than ten days, persons receiving unemployment benefit or assistance from the poor laws, or disabled by an industrial accident or in the war, and necessitous persons suffering from tuberculosis or venereal disease.

The Decree of July, 1930, introduced a new principle into the German insurance scheme—that of requiring the insured person to make a direct payment towards the cost of medical treatment. He must now before first seeing his doctor obtain from his society a treatment card (*Behandlungsschein*), for which he pays 50 pfennigs. But the payment is made only once for each illness, and it is not required from the persons mentioned in the preceding paragraph.

By the "treatment card" method, which has been adopted by some of the Austrian and Danish societies as well as in Germany, the insured person makes his payment towards the cost of treatment before the treatment is given. There is, however, another method of prepayment, one by which the insured person purchases books of special stamps from his society, and attaches one or more to the medical certificate he receives from his doctor. This system has been in operation since 1928 in the Swiss Canton of Soloturn, and has brought about a reduction both in the number of cases treated and in the duration of treatment, with a corresponding reduction in cost. The value of the stamp is fixed annually by the society, and the number of stamps attached to the certificate varies with the kind of treatment given; one stamp is required for an ordinary consultation, two stamps for a domiciliary visit, and six for a night visit. The value of the stamps used must not exceed 25 per cent. of the cost of the service rendered.

The stamps system is in operation also in Luxembourg, where the insurance societies are empowered to require the insured persons to pay a share, not exceeding 25 per cent., of the cost of treatment, but, with few exceptions, the societies have applied the requirement only to the dependents of the insured. The price of the stamps varies in the different societies: in one of the largest it has been fixed at two Belgian francs for a consultation and three francs for a domiciliary visit.

POST-TREATMENT METHODS OF PAYMENT.

There are two methods by which the insured person makes his payment after receiving treatment. By one method, which has been adopted by the Canton of Geneva, and by some Austrian societies, the society collects from the insured person the amount payable by him after he has received treatment. In practice considerable difficulty is experienced in collecting the sums due, arrears are common, and it is said that the system can be recommended only when the employer is willing to deduct the required payments from his employee's wages.

Another method is for the insured person to pay the doctor direct, as in private practice, and then recover from his society a certain proportion of the cost. This is the method by which the doctors are remunerated under the French insurance law. The insured person pays his doctor's bill and recovers from his society a sum which varies with the means of the patient from 80 to 85 per cent. of the total sum payable, that sum being calculated not on the actual amount charged or paid, but on a tariff of fees laid down by the society. A similar system is in operation in Norway.

There is evidence that insurance costs have been reduced by requiring the insured persons to make a direct payment towards the cost of treatment, and in Dr. Augustin's view it is the most effective method that has yet been devised to limit expenditure on health insurance. But it cannot be denied that to some extent the method reimposes between doctor and patient the barrier of the fee—a barrier which it was one of the aims of national health insurance to remove, and it may deter the poorer patients from seeking the medical care they may badly need. Cost reductions that have this effect may in the long run prove to be but false and mistaken economies.

References to Regional Medical Officers.

"Some time ago," writes Locum Tenens, "I took temporary charge of a practice containing 2500 panel patients. The doctor had scarcely started when a shower of reference forms began to fall on me at the rate of three and four a day to the number of five and twenty, one being, for a case of double optic atrophy. Records were well kept but in some cases it was difficult for a stranger to identify the particular person; one such I chased over the breadth of a county parish to find that he had been at work for some time. The final result of this expenditure of time and stationery was that one person was declared fit to work and she was a comical old woman who seemed almost unemployable. The doctor had a good laugh when he returned, but it was not very laughable for me."

INSTITUTE OF RAY THERAPY.

DURING its second year of work this Institute in Camden-road, London, has made steady progress; since January of the present year 455 new patients have been seen and over 20,000 treatments given. The number of practitioners referring patients to the Institute has also increased, and there was not a single exception to the rule that no patient is accepted unless provided with a letter from a qualified doctor. The system by which the practitioner is asked to suggest the grade of his patient's fee has worked well. As a result of financial depression many patients would have been unable to afford to pay for their treatments without help from approved societies and business firms. Since the Institute opened in March, 1930, a total of 2985 patients have been seen. Of the 1162 men and women discharged 63·9 per cent. were cured or improved, and 10·4 per cent. showed no improvement. Of the 319 children discharged, 68·4 per cent. were fit or improved, and only 4·1 per cent. showed no improvement. The chief affections treated have been rheumatic conditions, general debility, respiratory and nervous conditions, skin diseases, ear, nose, and throat complaints, and children's complaints. The medical staff incline to the opinion that infra-red rays may prove of value, especially in rheumatic conditions. The nucleus of a medical electricity and diathermy extension has been installed. Training courses in ray therapy are held every two months, and students are not allowed to sit for the diploma until they have worked at least 96 hours in the treatment rooms. The Institute has been recognised by the Society of Apothecaries as a training centre for the biophysical assistants' examination.

PANEL AND CONTRACT PRACTICE

INCREASED COST OF NATIONAL HEALTH INSURANCE.

IN all countries in which a scheme of national health insurance is in operation insurance administrators have during recent years been faced with the problems of increasing expenditure. Although the causes of the increase vary to some extent in different countries, there is one that is prominent in all—namely, an increase in the claims for sickness benefit. In this country attention was directed to the question by the publication two years ago of the Government Actuary's report on his "Examination of the Sickness and Disablement Experience of a Group of Approved Societies in the period 1921–27" (Cmd. 3548), from which it appeared that during that period the claims of men for sickness benefit rose by 41 per cent., those of unmarried women by 60 per cent., and those of married women by 106 per cent., while in all three categories the rise in claims for disablement benefit was considerably higher. In the Government Actuary's report on the "Third Valuation of the Assets and Liabilities of Approved Societies" (Cmd. 3978), published last December, further evidence was given of the seriousness of the position; and Sir Alfred Watson, in his concluding remarks, stated that the claims for sickness and disablement benefits had "risen to a level which in the case of men (regarding the system as a whole) precludes the expectation of any large amount of further surplus from savings in this direction, and, in the case of women, results in a loss of such dimensions as to call imperatively for measures of reconstruction."

German Experience.

The problems of increased cost in the different countries and the measures that have been adopted to deal with them are discussed in an interesting book on the medical aspects of health insurance which has recently been published by a German economist, Dr. Gisela Augustin.[1] In Germany, as in other countries, the cost of sickness claims has increased, and Dr. Augustin attributes it to a variety of causes. Owing to changes in the age and sex constitution of the population since the war the average age of the insured has increased, and there has been an increase in the number of women employed in insurable occupations. The insured persons have more incentives to claim benefit, for unemployment is prevalent and the rate of benefit has tended to rise—some societies before the recent measures of national economy paid a rate of benefit equivalent to 75 per cent. of the basic wage. Moreover, benefit is paid in respect of Sundays and public holidays as well as working days. Health propaganda, which is carried on vigorously in Germany, is said to be another cause of increased claims. The insured person hears so much about health that he becomes "health conscious," and seeks the services of his insurance doctor for the slightest real or imaginary ailment.

MEDICAL CERTIFICATION OF INCAPACITY.

By the insurance societies the increase of sickness claims is attributed largely to the lack of a sense of responsibility in the insurance doctors in giving certificates of incapacity for work. In Germany the payment per attendance system, which has been widely adopted, accentuates the difficulties experienced by doctors in dealing firmly with importunate claimants for benefit. Under this system the insured persons are not attached to particular doctors, as in Britain, but can consult any insurance doctor they prefer at the moment. If refused a certificate by one doctor the patient may go to another. Many claimants for benefit are referred by the societies to their medical referees (*Vertrauensarzte*), and there is a growing volume of opinion in favour of relieving the insurance practitioners of the duty of certification and transferring it entirely to the referees. It is contended that a doctor's business is to treat his patients: that is clinical work and he should stick to it. His attention should not be distracted from the professional work for which he is trained by having administrative duties, such as the issue of incapacity certificates, thrust upon him. Certification should be a matter for the *Vertrauensarzte*.

The medical profession in Germany are, however, against this proposal. It is urged that the decision on the question whether a patient's state of health necessitates his ceasing work is a clinical decision which is made as part of the treatment of the case, and can best be made by the practitioner responsible for the treatment. The practitioner having the patient under observation for treatment purposes is in a better position to decide whether he is or is not incapable of work than a referee, who sees him only once, and can have no first-hand knowledge of his reactions to the varying strains of industrial life. Treatment and certification, the doctors contend, should be in the same hands. In Denmark and Japan there are, it appears, no medical referees; certification is entirely a matter for the practitioner in attendance.

OTHER CAUSES OF INCREASED COST.

Increased sickness claims are not the only factors of the increased cost of health insurance that has been experienced in recent years. The expenditure on medicaments, appliances, institutional and other forms of special treatment has risen, and in countries such as Germany and Austria, where the insured persons are provided with a wide range of medical and ancillary services, expenses so incurred form an important proportion of the total cost. Large sums are spent in institutional treatment and the different forms of electrical treatment; and medicinal baths have attained a widespread and expensive popularity. Various methods for controlling such costs have been adopted, and according to Dr. Augustin the most successful is that of requiring the insured persons to participate in the cost of treatment—to make a small direct payment for the services rendered.

PARTICIPATION OF THE INSURED PERSONS IN THE COST OF TREATMENT.

In Germany the insured person has always been liable to pay part of the cost of the medicines and appliances prescribed for him. Usually his payment was fixed at 10 per cent. of the chemists' charges, but the insurance societies were empowered to raise this proportion to 20 per cent. In practice the requirement was not generally carried into effect, since the chemists refused to collect the small sums payable by the insured. Under the Presidential Decree of July, 1930, the insured person was required to bear the whole cost of a prescription not exceeding 50 pfennigs, and to pay that sum should the medicine prescribed cost more than 50 pfennigs. But the

---

[1] Die Arztfrage in der deutschen und ausländischen sozialen Krankenversicherung. Berlin: Richard Schoetz. 1931. Pp. 190. M.10.40.

Decree of December, 19[illegible], exempted from the payment all persons incapacitated from work for long periods, persons receiving unemployment benefit or assistance from the poor laws, or disabled by an industrial accident or in the war, and persons suffering from tuberculosis or venereal disease.

The Decree of July, 19[illegible], introduced a new principle into the German insurance scheme—that of requiring the insured person to make a direct payment towards the cost of medical treatment. He must now before first seeing his doctor obtain from his society a treatment card (*Krankenschein*), for which he pays [illegible] pfennigs. But this payment is [illegible] and it is not required from the persons mentioned in the preceding paragraph.

By this treatment card method, which has been adopted by some of the Austrian and Dutch societies as well as in Germany, the insured person makes his payment towards the cost of treatment before the treatment is given. There are, however, other methods of prepayment, one by which the insured person purchases books of special stamps from his society and gives one or more to the medical attendant [illegible] from his doctor. This system has been in operation [illegible] in the [illegible] of [illegible], and has brought about a reduction both in the number of cases treated and in the duration of treatment, with a corresponding reduction in costs. The value of the stamp is fixed annually by the society, and the number of stamps attached to the [illegible] varies with the kind of treatment given: one stamp is required for an ordinary consultation, [illegible] stamps for a domiciliary visit, and [illegible] for a night visit. The value of the stamps used must not exceed [illegible] per cent. of the cost of the service rendered.

The stamps system is in operation also in Luxemburg, where the insurance societies are empowered to require the insured person to pay a share, not exceeding [illegible] per cent. of the cost of treatment. [illegible] the societies have applied the requirement only to the dependants of the insured. The price of the stamps varies in the different societies; in one of the largest it has been fixed at [illegible] Belgian francs for a consultation and three francs for a domiciliary visit.

B.—[illegible] OF PAYMENT.

There are two methods by which the insured person makes his payment after receiving treatment. By one method, which has been adopted by the Union of Geneva, and by some Austrian societies, the society collects from the insured person the amount payable by him after he has received treatment. In practice considerable difficulty is experienced in collecting the sums due, arrears are common, and it is said that the system can be recommended only when the employer is willing to deduct the required payments from his employee's wages.

Another method is for the insured person to pay the doctor direct, as in private practice, and then recover from his society a certain proportion of the cost. This is the method by which the doctors are remunerated under the French insurance law. The insured person pays his doctor's bill and recovers from his society a sum which varies with the means of the patient from [illegible] to [illegible] per cent. of the total sum payable, that sum being calculated not on the amount charged or paid, but on a tariff of fees laid down by the society. A similar system is in operation in Norway.

There is evidence that insurance costs have been reduced by requiring the insured person to make a direct payment towards the cost of treatment, and in Dr. Engel's view it is the most effective method that has yet been devised to limit expenditure on health insurance. But it cannot be denied that to some extent the method interposes between doctor and patient the barrier of the fee, a barrier which it was one of the aims of national health insurance to remove, and it may deter the poorer patients from seeking the medical care they may badly need. [illegible]

References to Regional Medical Officers.

[illegible] Lorne [illegible] "I took temporary charge of a practice containing [illegible] panel patients. The doctor had recently started [illegible] at the rate of three and four a day to the number of [illegible] being for a case of [illegible]. Records were well kept, but [illegible] for a stranger to identify the [illegible] and that he had been at work [illegible]. The final result of this expenditure of time and energy was that one person was declared fit [illegible]. The doctor had a [illegible] but it was not very helpful for me."

INSTITUTE OF RAY THERAPY.

During the second year of work the Institute of Ray Therapy, Camden Road, London, has made steady progress: since January of the present year [illegible] new patients have been seen and over [illegible] treatments given. The number of practitioners referring patients to the Institute has also increased, and there has not been a single exception to the rule that no patient is accepted unless provided with a letter from a qualified doctor. The system by which the practitioner is asked to suggest the [illegible] of his patient's fee has worked well. As a result of financial depression many patients would have been unable to afford to pay for their treatments without help from approved societies and insurance firms. Since the Institute opened in March, 19[illegible], a total of [illegible] patients have been seen. Of the [illegible] men and women discharged [illegible] per cent. were cured or improved, and [illegible] per cent. showed no improvement. Of the [illegible] children discharged, [illegible] per cent. were fit or improved, and only [illegible] per cent. showed no improvement. The chief affections treated have been rheumatic conditions, general debility, respiratory and nervous conditions, skin diseases, ear, nose, and throat complaints, and children's complaints. The medical staff incline to the opinion that infra-red rays may prove of value, especially in rheumatic conditions. The nucleus of a medical electricity and diathermy [illegible] has been installed. Training courses in ray therapy are held every two months, and students are not allowed to sit for the diploma until they have worked at least [illegible] hours in the treatment rooms. The Institute has been recognized by the Society of Apothecaries as a training centre for the [illegible] physical assistants' examination.

CORRESPONDENCE

THE BALANCE OF DIET AND RENT.

To the Editor of THE LANCET.

SIR,—While I am grateful to Dr. Crowden for his illuminating article in your issue of April 23rd, I feel that I cannot be alone among your readers in being gravely disquieted by his conclusions and suggestions. There is, as he points out, no possible doubt that in a very large proportion of working-class households diet is inadequate and clothing is insufficient because high rents are being paid. No amount of contemplation of his article, however, can rob me of the impression that he regards the figures paid in rent as voluntary commitments of conveniently adjustable dimensions. If we take the four instances which he quotes (omitting for the moment the case of the unemployed man) we find figures for rent ranging from 10*s.* to 13*s.* 6*d.* The family which pays 11*s.* is solvent at the end of the week, but it is also in receipt of a considerably greater income than any of the others. In the present depressed state of industry, weekly wages of under £2 are regrettably common among artisans and labourers. Unfortunately, a rent of 10*s.* to 12*s.* per week is also a regrettably common thing, and it is a matter of extreme difficulty for any working man to find habitable quarters at a less cost for himself, his wife, and a couple of children. Dr. Crowden's unemployed man was in even worse case. Accepting the Board of Trade's scale of percentages, he was faced with the problem of finding, at a day's notice on the loss of his employment, rooms at a rent of five shillings and sixpence, and could not even then hope to supply himself and his family with the necessaries of life on an adequate scale.

It is folly to suppose that such people as these will, of their own desire, try to obtain accommodation in more expensive new houses. It is impossible for them to house themselves at a lower rent. What Dr. Crowden's paper has done is to put anew, and more strongly, the case against the slum landlord with his exorbitant sub-lettings and house-farming. No amount of warning of his victims can save them from what is, at present, their inevitable fate. The consequences of the rent-ramp have been perfectly demonstrated. Cannot the country which is suffering take more active steps than Dr. Crowden advocates?

I am, Sir, yours faithfully,

JOHN D. KERSHAW.

North Western Hospital, Hampstead, N.W.,
April 25th, 1932.

SURGICAL SCARLET FEVER.

To the Editor of THE LANCET.

SIR,—Prof. Okell has in his third Milroy lecture on the Inter-relationships in Streptococcal Disease cleared up what has been to me a source of interest and more or less mystery for over twenty years. During the years 1910–1912, when I was in the Public Health Service of the Manchester Corporation, we admitted to Monsall Hospital children suffering from burns who were said to have developed scarlet fever after being in the wards at Ancoats Hospital for some time. I was never able to make up my mind definitely as to the diagnosis. The chief characteristics were: (1) a well-marked punctate erythema with pyrexia; (2) the almost complete absence of throat symptoms; (3) the "ultra-scarlatinal" tongue, if one may use such an expression—after all these years I can still see the peeled tongue with the papillæ standing out like droplets of dew; (4) the children were not known to have been in contact with any previous case of scarlet fever, nor did they give rise to any secondary causes; (5) they desquamated but never very profusely; (6) none of them ever suffered from a so-called second attack, nor were there any complications, otorrhœa or mastoiditis.

That they were cases of scarlet fever Prof. Okell has, in my opinion, proved conclusively. They were infected through the raw surface of the burn, which was extensive in every instance. Since the infections were not faucial, hæmolytic streptococcus would be absent from the throat; consequently there would be no droplet infection to give rise to secondary cases, and we know, or at least we may believe, in view of recent research, that they need not have been infected from a previous case of scarlet fever. That they did not give rise to others of their class was due to the excellent aseptic practice carried out at Ancoats. If strict asepsis could be assured I see no reason why such cases need be moved to a fever hospital, since we now believe droplet infection to be the chief, if not the only means of spread, and streptococci cannot rise from the surface of a wound.

I have at present under my care in the Borough Infectious Disease Hospital, Northampton, a boy, aged 11 years, who at Christmas received a severe scald on the right leg extending from the knee to the ankle. On March 31st, when the scald was nearly healed, he developed a temperature and rash and was notified as suffering from scarlet fever. Here again there was no history of his having been near a known case of scarlet fever, as he had been away from school and confined to the house. On admission to the isolation hospital on April 1st there was a raw area about one inch by three-eighths in the middle of the thin scar on the outer side of his leg. He had a temperature of 100° F., a well-marked punctate erythema, furred tongue, but practically a normal fauces with no complaint of sore-throat. On April 6th there is a note on the case-sheet, "Tongue typical of scarlet fever. The leg is now healed, and the boy is up with no sign of any complications."

I am, Sir, yours faithfully,

STEPHEN ROWLAND, M.D.,
April 25th, 1932. Medical Officer of Health, Northampton.

TRAINING IN TUBERCULOSIS.

To the Editor of THE LANCET.

SIR,—To those specially concerned with the study of pulmonary tuberculosis, and responsible for the teaching of undergraduates and post-graduates, the leading article in your last issue will come as a welcome stimulus. The committee of the Joint Tuberculosis Council has called attention in general terms to one of the main defects in our system of training, but it is doubtful whether the majority of the profession, still less the public at large, are sufficiently aware of the seriousness of this question and of the extent to which it affects the national well-being. The arrangements available in the various schools of the United Kingdom for training medical students in the diagnosis and treatment of pulmonary tuberculosis are for the most part inadequate. There are—and this is the crux of the matter—only four centres, viz., Manchester, Sheffield, Edinburgh, and Glasgow, at which the existing course of teaching in this subject forms a compulsory part of the curriculum for undergraduates. Instruction in other schools may be admirable, but attendance on the courses is voluntary. In centres where no such facilities are offered in the teaching hospital itself, but where ample clinical material and organisation exists in the municipality, there is a lack of adequate coöperation between the medical school and the municipal authorities, nay there is even a feeling on the part of the latter of jealousy of any desire that may be expressed by the University teachers to exploit the existing machinery in the interest of their students. I would go so far as to say that, although in this country there is potentially an abundance of opportunity for the training of the future practitioner in the art of dealing with a disease which kills at least 40,000 of the population every year, yet the vast majority of those who enter general practice, and not a few in the ranks of the consultants, are lamentably incompetent to manage the problem of the phthisical patient, and this through no fault or lack of intelligence, but simply from want of necessary training.

The futility of such a state of affairs is the more apparent when considered in relation to the annual expenditure in the country on the various forms of tuberculosis work. According to the annual reports of the Ministry of Health the total amount of money so spent by the local authorities is over three and a quarter millions a year. Statistics of the after-history and results of sanatorium treatment are discouraging. Even in those at which for the most part only patients of really favourable type are accepted, nearly 40 per cent. of sputum-positive cases are dead at the end of five years, and in less eclectic institutions the results must be worse. Every experienced superintendent makes the complaint that he does not get the most suitable cases, the reason being that the practitioner does not realise the stage of disease at which sanatorium treatment is likely to be of real and lasting benefit. The waste involved in sending to a sanatorium patients who could be better treated in hospital is enormous, yet many cases are so disposed of because the practitioner who first handles them cannot visualise the different types of disease, nor does he grasp the clinical criteria which determine the question of activity or quiescence. Thus it is that a vast amount of public money is yearly thrown away upon our present system of dealing with tuberculous patients, a system which is ineffective from a national point of view, since it does not demand from everyone concerned a fundamental knowledge of elementary clinical principles.

Yet when the plea is advanced for making the study of this disease a compulsory part of the medical student's training, it is met with determined opposition from teachers in our medical schools unwilling to add to the burden of students labouring under an overloaded curriculum. To these I would reply that the *problem* of training in tuberculosis is an integral part of the problem of medical education as a whole, for the reform of which all students and most teachers are clamouring. We need less theory and more practice, less of academic training and more of clinical apprenticeship. Sooner or later the curriculum will have to be radically reformed, and the sooner the better.

I am, Sir, yours faithfully,

MAURICE DAVIDSON, M.D., F.R.C.P.

Wimpole-street, W., April 23rd, 1932.

SCARLET FEVER AND STREPTOCOCCAL INFECTION.

To the Editor of THE LANCET.

SIR,—In his third Milroy lecture which you published last week Prof. Okell says:

> "It is not necessary to marshall the evidence in favour of the belief that scarlet fever is entirely an infection with hæmolytic streptococci. This has been done many times during the past few years and it would be difficult to find any serious flaw in the evidence."

This statement leads me to bring forward a point which has for long seemed to me to have escaped the notice of the bacteriologists with regard to scarlet fever. Surely from the clinical and epidemiological standpoints one of the most characteristic features of this disease is the fact that it confers a long-standing if not *lifelong immunity to reinfection!* Persons who have passed through an attack of scarlet fever may work through virulent epidemics and the chance of reinfection is slight. In this respect scarlet fever differs so essentially from the known streptococcic infections—e.g., erysipelas and impetigo—that it seems to me we ought to hesitate before accepting *as the cause of scarlatina a streptococcus which the* bacteriologists consider to be merely a sub-variety or race of the ordinary pathogenic streptococci.

I am, Sir, yours faithfully,

ARTHUR WHITFIELD.

Harley-street, W., April 25th, 1932.

PSYCHOLOGY AND MEDICINE.

To the Editor of THE LANCET.

SIR,—While I do not dispute with Dr. Brown that individual psychology and psycho-analysis may each appear to have special therapeutic validity on special occasions, and in the use of special physicians, I beg to state that, in the opinion of individual psychologists, the differences between psycho-analysis and individual psychology are not merely technical and those of procedure, or selective applicability, but basal. So far as we see, there are differences in respect of the great problems fundamental to all philosophies and science. Psycho-analysis appears to us realist, in the scholastic sense; individual psychology is certainly conceptualist, if not nominalist. Psycho-analysis seems to admit the validity of the four Aristotelian causes; individual psychology that of the *telos* only. Adler is distinctly a "no-classes" man; Freudians classify and adhere tenaciously to their classes. Adlerians are pragmatic monists; are not Freudians dualists? Individual psychology admits freewill, subjectively, even if acknowledging the objective appearance of determination. What has psycho-analysis to say?

But, most importantly, whilst individual psychology deals with nothing *below* the Plimsoll level of the *complete individual*, the psychosomatic unity—building upwards, synthetically and holistically—psycho-analysis, true to its name, breaks the individual down into something less—a hierarchy of super-ego, ego, id, censor, and what not. No doubt Dr. Brown may suggest that reconciliation of even these differences is not impossible, but we think that such could only be brought about by solution in the absolute relative. Again, Dr. Brown may claim to be already there. In such case, individual psychology, believing to have the last word, would regard his claim as a "fictive ideal." And our differences would remain. But we should still be friends.

I am, Sir, yours faithfully,

F. G. CROOKSHANK.

Wimpole-street, W., April 23rd, 1932.

THE TOLL OF THE ROAD.

To the Editor of THE LANCET.

SIR,—Dr. R. J. Clausen, in your issue of April 16th (p. 854), aptly calls attention to the number of largely preventable injuries and fatalities caused by motor traffic. It is seldom that such disasters now arise from mechanical breakdown in the cars concerned. A large proportion is caused by what Scotland Yard describes as "carelessly crossing the road by pedestrians." At a recent inquest regarding a fatal motor accident the coroner said: "People make a sudden *decision to cross a road, and they take risks which* they would not normally take. Until they can be educated not to take such risks, it is difficult to see how a great number of accidents can be prevented." With an experience of 20 years' almost daily motoring in both town and country one confirms the opinion that by putting into practice one simple rule the pedestrian could obviate a large proportion of accidents. The simple rule is—never attempt to cross a road—ordinary two-way traffic—without first looking to the *left* and then to the *right*. The important reason for looking to the right-hand last is because one always steps first into the line of traffic coming from the right. This rule, after a day or two's practice, becomes automatic habit—it is life-saving.

I am, Sir, yours faithfully,

W. W. SHRUBSHALL.

Burgess Hill, Sussex, April 20th, 1932.

ERGOTISM AND VITAMIN-A DEFICIENCY.

To the Editor of THE LANCET.

SIR,—The similarity between convulsive ergotism and the symptoms of vitamin-A deficiency, noted by Prof. E. Mellanby,[1] reminds us of a chance observation made by us over a year ago, when we were testing the vitamin content of an oil. For this purpose we used young white mice instead of rats, the usual test animals, as a sufficient number of young growing rats was not available. Sixteen mice, 25 to 29 days' old, were kept on the following diet, deficient in fat-soluble vitamin A:

Fat-free casein	18 per cent.
Starch	78 „
McCollum & Simmonds's salt mixture	4 „

brewers' yeast being added, 6 g. for every 100 g. of the mixture.

After three weeks the mice began to show a loss of weight and hair. Three days later one of them developed a dry gangrene of its hind limbs, and within a few days three other mice developed a similar condition. Finally, the gangrenous part of the limbs of all these animals dropped off. Except for this condition and the consequent inconvenience, the animals looked well and took their nourishment like the rest. We suspected ergotism, and tested our supply of starch by microscopical, chemical, and biological methods, as described by R. Kobert,[2] A. W. Blyth,[3] and Dilling and Kelly,[4] with negative results. All the affected mice died about seven weeks from the commencement of the experiment, and the post-mortem examination did not supply any explanation for the gangrene. No growth occurred on the ordinary media inoculated with the blood of these animals. Microscopic sections of different tissues and organs threw no light on the condition. There were no lesions resembling those found in ectromelia, the virus disease of mice, recently described by J. Marchal.[5]

The condition could not be produced again in another batch of mice of the same age, placed under similar conditions, and so could not be studied further. We cannot, therefore, say whether this was another hitherto unknown infection in mice, whose resistance was diminished by vitamin-A deficiency. We shall be glad to hear about similar observations made by any of your readers.

We are, Sir, yours faithfully,

A. S. PARANJPÉ, M.D. Heidelberg, M.B., Ch.B. Edin.,

G. K. GOKHALE, M.B., B.S. Bombay,
Assistant in the Department.

REFERRED PAIN IN VISCERAL DISEASE.

To the Editor of THE LANCET.

SIR,—In your issue of April 16th Mr. John Morley asserts that I use the term viscero-sensory reflex in a sense very different from that given to it by Mackenzie, its originator. According to Mr. Morley, Mackenzie defines his viscero-sensory reflex as superficial pain and hyperalgesia referred to the somatic sensory nerves of the skin and subcutaneous tissue of the abdominal wall resulting from violent stimulation of the afferent nerve-endings in the viscera. But Mackenzie's conception of the viscero-sensory reflex was a very much wider one than that quoted by Mr. Morley.

Referring to Mackenzie's work, "Symptoms and their Interpretation" (3rd ed.), I find on pages 42 and 43 a case of appendicitis described in detail in which Mackenzie found no hyperalgesia of the skin or subcutaneous tissue but a viscero-sensory reflex in the increased sensitiveness of the sensory nerves supplying the muscles over the right iliac fossa and the erector spinæ. On page 65 I find Mackenzie declaring that hyperalgesia of the muscles is far more common than hyperalgesia of the skin; on page 66 is a description of hyperalgesia of extra-peritoneal tissue—mamma, testicle. On pages 68 to 70 Mackenzie mentions hyperalgesia of certain vertebræ in visceral disease. On page 181 Mackenzie mentions the extreme hyperalgesia of the tunica vaginalis in certain cases of renal colic. Obviously the viscero-sensory reflex as Mackenzie conceived it embraced every tissue of the abdominal wall he was able to test and prove, not only skin and subcutaneous tissue as claimed by Mr. Morley.

Mr. Morley says that the complete immobility of the gut described in his work is due to the splanchnic inhibitory reflex which has nothing in common with the mechanism conceived by Mackenzie as the viscero-sensory reflex, but I suggest to Mr. Morley that if stimulation of the abdominal wall elicits a visceral response that phenomenon itself is proof of the existence of a viscero-sensory mechanism, even if it be labelled a splanchnic inhibitory reflex. And if I may repeat the query in my letter published in your issue of April 2nd, how other can the phenomenon of visible peristalsis elicited by pinching up the skin and subcutaneous tissue of the abdominal wall in certain cases of intestinal obstruction be explained than by the existence of a viscero-sensory *reflex*?

I am, Sir, yours faithfully,

St. Leonards-on-Sea, April 22nd, 1932. DAVID LIGAT.

THE PROBLEMS OF MARRIAGE.

To the Editor of THE LANCET.

SIR,—In view of the proposal of the British Social Hygiene Council to establish a Personal Problems Bureau and the criticism of this proposal in your correspondence columns we should like you to know that at a recent meeting of the North-West London Medical Society a resolution was carried that before attempting any independent means to give effect to the considered opinions of our members, our first efforts should be directed to securing the coöperation and the assistance of established medical organisations. The facts are these :—

1. The British Social Hygiene Council, a lay organisation with certain honorary medical advisers on its board, has published details of a proposed bureau of personal problems. These suggest to our minds that the project is of a questionable nature, judged from what has hitherto been considered as strictly ethical, and the proposed bureau might be regarded as a well thought-out attempt on the part of certain practitioners to secure to themselves by indirect means, including lay press publicity, access to the public for the purpose of securing patients.

2. It has been brought home to us increasingly in recent years that conduct, which in the case of an individual practitioner would almost certainly be regarded as questionable from the ethical point of view, is rarely challenged when similarly practised by groups of practitioners working under the control of lay bodies interested in medical matters.

3. It is in our opinion definitely contrary to the interests of medical practice that this state of affairs should be allowed to continue without an immediate and representative inquiry; and if the results of such inquiry warrant, any such practitioners, without personal malice, should be cited before the General Medical Council as test cases for the purpose of securing definite rulings and guidance on these matters. Finally, we are strongly of opinion that an independent Council of Legal Information should be set up to advise practitioners who contemplate engaging in new forms of medical activity on ethical problems from a strictly *legal* standpoint, as we do not feel that the present facilities for this advice are reliable or sufficient.

We are, Sir, yours faithfully,
For the Committee of the North-West London
Medical Society,
L. M. GREEN,
Hon. Secretary.
GILBERT R. A. ARMSTRONG.
President.

MYASTHENIA GRAVIS.

To the Editor of THE LANCET.

SIR,—The two following cases may interest "Inquirer," who writes in your issue of April 16th. The first patient was a man of 57 who had very severe symptoms of myasthenia gravis and whose case I described in full in the *British Medical Journal* of Jan. 17th, 1925. To my amazement I find that he is well and hard at work at the present time and that, in fact, the improvement in his health coincides with his taking the juice of six lemons every day. This he tried as a last resort at the end of 1924 when he had been regarded by myself and several other physicians and at least two neurologists as quite hopeless.

The second, and more recent, case is that of a man of 28 in whom the disease developed rather rapidly, so that at the end of two years—i.e., about last November—he was so weak that he was unable to walk and after uttering a few words his voice completely gave out. The usual regurgitation of food was liable to occur owing to paralysis. Here again the case appeared to be desperate, and in the light of my experience of the first patient I suggested his trying these massive doses of lemons. At the same time, however, the patient was put on ephedrine grs. 3 thrice daily so that the cause of his dramatic improvement may be one or the other, or for that matter, neither. Be that as it may, he is now able to drive a car and can talk and eat just like a healthy person.

In a disease of this rarity and subject to remissions, it is impossible to get a sufficient number of cases to investigate scientifically the value of any so-called cure, and in submitting these notes I fully realise their consequent lack of value; nevertheless, when faced with this appalling condition, it is obvious that any treatment which has possibly done good should be tried, provided that it cannot do harm.

I am, Sir, yours faithfully,
A. H. DOUTHWAITE.
Harley-street, W., April 20th, 1932.

THE DURATION OF THE RED LOCHIA.

To the Editor of THE LANCET.

SIR,—In my article of March 12th I was intent on stating a fact, and carefully avoided putting any interpretation on the findings. Your correspondents have made use of the significance of the prolongation of the discharge: Dr. Remington Hobbs to advocate glycerin drainage, and Dr. Morris Johns to allege that such proceedings treat a disease which does not exist. Now, if by red lochia Dr. Hobbs means a bright red vaginal discharge after childbirth, it will be readily agreed that a prolongation after the seventh day, and certainly after the twelfth day, is an indication of a uterine abnormality which demands treatment. On the other hand, in my article it was carefully explained that under the heading of red lochia any red or reddish-brown discharge after childbirth was included, even if the discharge had been temporarily absent during the last few days in hospital, but had reappeared on the patient's resuming household duties. By this standard 86 per cent. of hospital patients—the great majority of whom showed no other sign or symptom of abnormality—had a prolongation of coloured lochia beyond ten days. The use of the term "abnormal" in describing such a large majority of apparently healthy women is surely a perversion of the meaning of the word; it therefore seems unreasonable to institute artificial drainage of the uterus for this one reason alone. It is interesting to read Smellie's account of the lochia:

> ". . . in some patients the red lochia disappears on the 1st or 2nd day: but in others, though rarely, it continues more or less to the end of the month; in one woman it ceases very soon; in another, it flows during the whole month: yet all the patients shall do well."

I am, Sir, yours faithfully,
CHASSAR MOIR.
Obstetric Unit, University College Hospital, April 26th, 1932.

NOVEMBER HANDICAP SWEEPSTAKE.—The official auditors report that the receipts for the Irish sweepstake on the November Handicap were £2,941,851. The cost of administration was £262,000, or nearly 9 per cent., inclusive of £85,837 paid to the promoters. The largest item of expenditure was £103,000 for salaries, wages, and State insurance.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS.

HOME OFFICE AND INDUSTRIAL DISEASES.

Sir **HERBERT SAMUEL** (Home Secretary), speaking on the Home Office vote, said that his department had always been active in increasing the protection of workers in industry, and within the last year new codes of regulations had been issued dealing with the building trade, sugar factories, and chromium painting. Regulations were continually being elaborated to prevent industrial disease. Within the last few months the Silicosis and Asbestosis Act had been put into operation, the effect of which should greatly increase the safety of workers in those industries. In the factories safety organisations were being promoted, and not far from the House of Commons, in the Horseferry-road, there was an industrial museum which contained large numbers of appliances and devices of various kinds for safeguarding the health and safety of the workers.

SWEEPSTAKES.

Referring to the Irish hospital sweepstakes, Sir H. Samuel said that there had been five of those sweepstakes between November, 1930, and March, 1932, and the public in the United Kingdom and throughout the world had subscribed to those sweepstakes no less than £13,800,000. Of that sum they had received back in prizes £7,700,000. The expenses and commissions of the sweepstakes had cost £3,300,000, and the Irish hospitals had received £2,800,000. So far as Great Britain was concerned a calculation had been made based upon the proportion of the prizes received in this country which were known, and on that basis it might be estimated, though the precise accuracy of the figures could not be guaranteed, that the people of Great Britain had subscribed to the five Irish sweepstakes £9,500,000, and they had received back in prizes £5,000,000. The commissions of sellers of tickets in Great Britain had amounted to £1,600,000, and there had been a sum transferred from Great Britain to Ireland on balance of about £2,750,000. That made them realise how necessary it was that the whole subject should be subjected to a very close examination. (Cheers.) And it was high time that the Royal Commission should be appointed.

PITCH CANCER IN GLAMORGAN.

Mr. **GRENFELL** drew attention to the class of diseases which affected the respiratory organs and which, he said, were very prevalent in his own county of Glamorgan. He asked whether the Home Secretary was satisfied that his medical advisers were treating the problem of silicosis and anthracosis in the proper way. He had been in communication with the Home Secretary on the question of pitch cancer. He was firmly convinced that the incidence of this particular form of cancer among men engaged in certain processes in the Swansea district proved the connexion between the elements of coal gas and the condition of cancer. The cancer starting in the nasal passages became visible after a time, and ultimately grew upon and destroyed the membranes and soft tissue of the upper nasal region and resulted in death. For a long time the question of what was commonly called pitch cancer, epitheliomatous cancer, was inquired into. In the patent fuel industry a large number of men were affected. There were frequent cases of unsightly and painful cancerous growths. By preventive regulation the number of cases had been reduced almost to nil. He asked the Home Secretary to press forward his inquiries into these matters. He suggested that he should institute a kind of pathological survey of the men engaged in these processes where cases had been reported.

THE MEDICAL SIDE: RESEARCH.

Lieut.-Colonel **FREMANTLE** said that the medical side of the Home Secretary's estimates was almost of as great importance to the health of the nation as that of the Ministry of Health. If, however, as had been suggested, the Home Secretary were to undertake an inquiry into the causes of the different industrial diseases a sectional inquiry of that kind would be of very little value, and would lead to much overlapping. For instance, cancer must be taken in relation to the whole consideration of the prevention of that disease. That was a subject which was not rightly dealt with even in the Ministry of Health, because research was primarily in the hands of a body under the Privy Council—the Medical Research Council. That was necessary, because if research was placed in the hands of any one department it was essentially tendentious. That was not the way to arrive at the scientific truth. Research ought to be properly conducted by a body out of the reach of the Government departments. But the Government departments should be very active in stimulating such research and contributing what special factors they could in the circumstances. Such activity might be very valuable now that there had been a suggestion that cancer was attributable to a certain form of gas produced in certain industries, and information should be sent to the right quarter. The work of cancer research was conducted very largely by two particularly centralised bodies—the British Empire Cancer Campaign, and the Imperial Cancer Research Board. The same applied to other industrial diseases. There ought to be proper coördination between the different Government departments which had to deal with the health of the people. There had been an enormous amount of wasted energy both in administration and in inquiry of various kinds, and a great deal of overlapping. Medical men considered that physical questions, like housing and actual physical illness, had a great deal to do with the causation of crime. The health organisation of the country was very valuable in that connexion. At the same time, medical men were laying more and more stress upon the mental side of health, and in connexion with health they recognised that it was much more important than the physical side, although the physical side must not be neglected. They had to take into account the increasing physical and mental dangers at the present time. The rush and hurry, the stress and noise as a result of modern inventions, and the acceleration of communications, were largely responsible for a great deal of the mental illness, and indirectly, therefore, were tending towards mental crime. He hoped that the attention which was being paid to these matters in connexion with the Mental Treatment Act, and mental treatment generally, would reflect itself sooner or later in the possibility of preventing crime at a very early age or diminishing the modern conditions tending in the same direction.

Government Reply.

Mr. **OLIVER STANLEY** (Under Secretary for Home Affairs), replying to the debate, said he agreed that the position in regard to miners' nystagmus was not one which could give them any satisfaction. The Home Office were giving further consideration to that terrible disease, and further investigation was being pursued in regard to it. As regarded the rather worrying type of cancer referred to by Mr. Grenfell, the Home Office had been making inquiries and it was certainly unfortunately true that those inquiries had revealed an unexpected existence of cancer among persons employed at works in the hon. Member's district. The inquiries had thrown no real light on the question as to how the disease was caused, nor had they established any connexion between that disease and the occupation of the people suffering from it. The employers were much disturbed by the discoveries, and they had engaged the services of an eminent pathologist to carry out further investigations.

EDUCATIONAL HEALTH SERVICES.

The House of Commons on April 18th went into Committee of Supply on a vote of £26,892,676 for the Salaries and Expenses of the Board of Education. Captain BOURNE, Deputy-Chairman of Committees, was in the chair.

THE PRESIDENT'S STATEMENT.

Introducing the vote, Sir D. MACLEAN, President of the Board of Education, said that there was one item on which local authorities were proposing some increase of expenditure—namely, health services. He did not suppose anybody would be inclined to criticise their action, because he thought that the value of the work of the School Medical Service was nowhere disputed. Health was a fundamental essential of a good education and of national well-being. He had no doubt that children who were leaving school to-day were healthier and fitter than those who left 20 years ago. On the other hand, it must be recognised that complaints were made of the physique of many young men by employers. He understood that the Army authorities were concerned at the physical condition of recruits. These complaints undoubtedly pointed to what was a very serious national problem—namely, the risk of physical deterioration during adolescence after leaving school. That was a problem which is beyond the control of the school authorities. Its gravity was not so widely appreciated as it should be, though workers amongst the adolescent were fully alive to it, and a warm tribute should be paid to the voluntary efforts which were being made to tackle it through boys' and girls' clubs, boy scouts, girl guides, and the many other similar activities.

In connexion with this problem of the health of the adolescent, he would draw particular attention to the recommendations in regard to education which were contained in the recent report of the Royal Commission on Licensing. The Commission, though composed of persons of the most divergent standpoints, were unanimous in emphasising the importance which they attached to suitable instruction in regard to alcohol in the schools of the country. Their unanimity on such a point was a remarkable fact which added greatly to the importance of the recommendations. They would, he was sure, receive the closest consideration of all concerned. Amongst other things the Commission fully endorsed the view that the instruction should form part of the general course of instruction in health. In furtherance of this view he was taking steps to have the Board's syllabus on "The Hygiene of Food and Drink" and also their volume of "Suggestions for Health Education" combined into a single pamphlet.

One other matter affecting health might be of interest to Members who often put questions on the subject of the use of milk in schools. Recent experiments had emphasised the very great value of milk as an addition to children's diet. It was therefore gratifying to note that about 800,000 children were now receiving a daily ration of milk for which they paid 1d., as compared with 350,000 two years ago; the activities of the National Milk Publicity Council were mainly responsible for this satisfactory increase. In addition, local education authorities provided free milk to 120,000 children whose parents could not afford to pay for it. So that in the aggregate nearly 1,000,000 children in the elementary schools were receiving at least a glass of milk a day.

PLAYING FIELDS.

Mr. MORGAN JONES said he was very much interested, as many others were, in the very influential campaign conducted in the last four or five years for providing national playing fields. It was odd that many schools in the heart of the country had less playground accommodation than many schools in thickly populated urban areas. That was a state of affairs which must receive attention, and he hoped that the Board of Education would keep its eye upon the point. The sanitary accommodation of schools also required to be looked into.

Mr. MCENTEE said that children in the special schools and in the schools for physically and mentally defective children were all suffering because the education committees in their areas had not taken advantage of opportunities offered to them. He was sure that there were plenty of sources of revenue still to be tapped without tapping the source of education and inflicting an injustice on children for the remainder of their lives. The present Government would go down to history as the Government who had robbed the children of their childhood.

TEACHERS AND DOCTORS: DANGER OF MASS NEUROSIS.

Dr. O'DONOVAN said that he hoped the time would come when the teaching profession would be as conscious not only of its responsibilities but of its powers as the medical profession. No one kicked harder than doctors at orders from Whitehall, and if only teachers were inoculated with this mulish virus it would be better for education. They could not undertake a review of the educational services without paying a tribute to the great work of the school medical officers and the efficient work of school nurses. But those were dreadful dead ends of professional life, and unless more openings were made by which the keener members of those services could rise to better positions they would cease to attract the best of their nurses and the best of their doctors. The best doctors and nurses, though content with their pay, desired bigger fields for their energies and abilities than the school medical service afforded. They should not take pride either in the magnitude of their school clinics or in the number of their school doctors; they represented the extent of their failure in the home. If they needed many more nurses to see that the children were free from ringworm and parasites and minor disorders it was evidence of a deficiency in the home work. It would tend to make much of our school medical services unnecessary if mothers had the instincts of the race and had better homes in which to bring up their children. It would not be altogether lamentable if a reduction of the grants from Whitehall led to a greater independence on the part of local authorities. If there was anything that was going to destroy modern civilisation it was not Capitalism, Socialism, or human perversity, but a general mass neurosis. If they watched carefully the writings of the medical profession they would gather that doctors feared a development of mass neurosis more than they feared the growth of cancer or consumption. If they looked at the school records and the records of school teachers they would find that nervous maladies predominated and reached a greater figure than in almost any other human occupation. If the teachers developed neurosis the pupils were bound to contract it. A study of the lower tone of the children in our elementary schools was most urgently called for.

INFLUENCE OF HOME CONDITIONS.

Lieut.-Colonel FREMANTLE said that Dr. O'Donovan had emphasised the point that the medical profession were not simply looking after the health of the children but that the education of the spirit had been the guiding line for the individual, while the body was merely the machine through which the spirit was able to take effect. They wanted education in the wider sense. They were responsible for the education of the body and the mind and they wanted to educate children in such a way as would lead to the development of the right spirit. As an old medical officer of health he (Colonel Fremantle) was particularly concerned with the health side of education, both mental and preventive. There were two sets of people engaged in education who were responsible for the preventive side—the teacher and the parent. Everything they could do to interest these two sets of people had been done. But what was most important was the development of family health. In his view the school and the home were too much divorced. The mental side was liable to be forgotten in considering the health of school-children. It was useless for one Government department to be considering its own side of the problem. All the different sides should be considered. The school for mentally defective children had to be associated with the mental hospitals and the work of mental treatment under the Board of Control. The work of the Ministry of Health and the Home Office also came in as well. They had to look into the causes of the growing neurosis in the population which had been referred to in that debate. The birth-rate had been brought down to a very small figure, the death-rate was reduced to a minimum, and the infant mortality-rate was down perhaps to the lowest point, but they had to deal with a generation previously afflicted with nervous maladies. One of the chief causes was the appetite of the children for an unnatural amount of movement and activity. A great deal of it was natural, and it was difficult to know where to stop. They had to give the children themselves the seeds of a love of quiet which might afterwards be a valuable influence in trying to resist the tendencies which made for neurotic troubles. He could see no signs of the health side of education being in any way deteriorated by the present economies.

Progress was reported.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 20TH.

Adulteration of Milk.

Brigadier-General CLIFTON BROWN asked the Minister of Health whether he had yet consulted with the Ministry of Agriculture on the Adulteration of Milk Act; and whether he proposed to make any alterations or amend the Act so as to make the law more equitable than at present.—Sir E. HILTON YOUNG replied: This matter has been discussed with my right hon. friend, the Minister of Agriculture, but the consideration of any proposals for legislation relating to the composition of milk must be postponed pending the recommendations of the Milk Reorganisation Commission.

THURSDAY, APRIL 21ST.

Factory Inspectors' Report.

Mr. RHYS DAVIES asked the Home Secretary whether he would expedite the publication of the Factory Inspectors' Report for 1931, so that it might be available for the purposes of consideration and debate before the House rose in July.—Sir HERBERT SAMUEL replied: I will endeavour to expedite the issue of this report.

Education of Deaf Children.

Sir WILLIAM JENKINS asked the President of the Board of Education the number of deaf children in England and Wales; the compulsory age of attendance at school; what accommodation was available; and what was the cost per pupil for training.—Sir DONALD MACLEAN replied: On Dec. 31st, 1930, the latest date for which figures are available, the number of children, in England and Wales, ascertained by school medical officers to be deaf was returned as 3621, of whom 1915 were boys and 1706 were girls. On the same date there were returned as partially deaf 1882, of whom 973 were boys and 909 were girls. The period of compulsory education for deaf children is from the age of 7 to that of 16. Special schools for the totally deaf provide accommodation for 4386 children, and in addition there are 222 places in schools certified for the partially deaf. It is estimated that the average cost of the education of deaf children is approximately £39 per child per annum in the day schools, and £72 in residential schools.

Mr. T. WILLIAMS: If these children have to remain for two years longer than ordinary elementary school boys and girls, is there any organisation to provide available opportunities for them when they are ready for work?

Viscountess ASTOR: Would the right hon. gentleman consider having compulsory education for deaf children a little earlier? It is found in Plymouth that if you get these children at school a little earlier it is far more advantageous.

Sir D. MACLEAN: With regard to the question put by Mr. Williams that matter is engaging the attention of the Board and the organisation of the Board takes a special interest in the matter. The question raised by Viscountess Astor would require additional legislation, and it is a very open question whether the parents of those unfortunate children would be willing to send them to school at an earlier age. At the moment I am not prepared to give any other answer to the question.

Mr. T. WILLIAMS: Seeing that accommodation is available for less than 50 per cent. of those children who are defective, will the right hon. gentleman require local authorities to provide accommodation for the remainder?

Sir D. MACLEAN: Not at present.

Mr. MCKEAG: Is the right hon. gentleman aware that purely mentally defective children are very often mixed up with deaf children at schools for the deaf, and that, if that were not the case, much more accommodation would be available for those who are merely deaf?

Sir D. MACLEAN: I will inquire into that point.

Mentally Defective Children.

Sir WILLIAM JENKINS asked the President of the Board of Education the number of mentally defective children in England and Wales, giving separate figures for boys and girls; what accommodation was available for their education and training, and where the institutions were situated; and what was the average cost per pupil for training.—Sir DONALD MACLEAN replied: On Dec. 31st, 1930, the latest date for which complete figures are available, the number of educable mentally defective children of school age, ascertained by school medical officers in England and Wales, was returned as about 32,100: 18,700 boys and 13,400 girls. It is known, however, that the actual number of such children is considerably larger. There is accommodation in special schools for about 16,600 children of this type, and I am sending the hon. Member a copy of the Board's List 42, which shows where the schools are situated. The average cost of education in these schools is about £23 per child, per annum, in day schools, and £67 in residential schools.

Blind Persons' Pensions.

Mr. HUTCHISON asked the Secretary to the Treasury how many blind persons were now receiving a pension under the Blind Persons Pensions Act; and how this total compared with the number of blind persons in the country.—Major ELLIOT (Financial Secretary to the Treasury) replied: The number of persons in receipt of pensions under the Blind Persons Act, 1920, on Dec. 31st, 1931, the latest date for which figures are available, was 24,387. According to the latest returns received from the local authorities, the number of registered blind persons in England and Wales was 52,727 on March 31st, 1929. Returns are now being obtained from local authorities of the number of registered blind persons in their areas on March 31st last. According to unofficial figures obtained from the Counties' Associations for the Blind there were 60,598 registered blind persons in England and Wales on March 31st, 1931. The number of registered blind persons in Scotland on March 31st, 1931, was 8621.

Mr. MAGNAY asked the Minister of Health whether his attention had been called to the recent increase in the numbers of registered blind persons in England and Wales; and whether he could state the reasons for this increase.—Mr. ERNEST BROWN replied: Yes, Sir. There has been a continuous increase in these numbers, but my right hon. friend is advised that this is probably due to more complete registration and does not necessarily indicate any actual increase in the number of blind persons. Many persons who have been blind for some time, but were previously unaware of the services provided under the Blind Persons Act, have been led to seek registration in order to obtain the benefits available under that Act.

MONDAY, APRIL 25TH.

Indian Medical Council Bill.

Mr. MORGAN JONES asked the Secretary of State for India the present position in respect of the Indian Medical Council Bill recently brought before the Indian legislative council by the Government of India.—Sir S. HOARE replied: The Bill was introduced in the Indian Legislative Assembly on March 23rd. I have not yet heard whether it has made any further progress.

Relief of Victims of Chinese Floods.

Mr. RHYS DAVIES asked the Secretary for Foreign Affairs whether he could give the House any further information regarding the relief work for the victims of the Yangtse flood; and what was the present attitude of His Majesty's Government in this matter.—Sir J. SIMON replied: In September, 1931, the Assembly of the League of Nations adopted two resolutions in regard to the floods in China, and the Council of the League instructed the secretariat to communicate copies to all the Governments. In response to this appeal many contributions were made directly to China, and in addition the following were notified to the League: Contributions in money were made by the Belgian and United States Red Cross, the Red Crescent Society of Turkey, and the Swedish Red Cross. Contributions of medicines, &c., were made by the University of Toronto, the State Serum Institute of Denmark, the Pasteur Institute of Saigon, and the Governments of Egypt, Indo-China, India, the Netherlands, the Netherlands East Indies, Norway, Poland, Spain, Sweden, and Yugoslavia. Contributions of medical personnel were made by the Governments of Egypt, the United States, Indo-China, the Netherlands East Indies, and Spain. In addition to these, contributions of various kinds were made by private organisations and individuals in several countries, including a monetary contribution from the Society of Friends in England. When the laboratory resources of China were organised in view of the need for vaccines and sera, all needed supplies were produced without difficulty, so that the health authorities found it unnecessary to accept many offers of this kind. Among contributions actually sent was one of anti-plague vaccine from the Government of India. The medical director of the health section of the League arrived at Nanking in September, and placed himself at the disposal of the Chinese Government and the Flood Relief Commission. He remained in China till late in December. Prof. Cinca and Drs. B. Borcic, C. L. Park, A. Stampar, and T. F. Huang, all of the League Health organisation, made a survey, gave advice, and organised anti-epidemic campaigns. All these activities were coördinated by Sir J. Hope Simpson, who at the request of H.M. Government placed his services at the disposal of the Chinese Government, and was appointed to be head of the National Flood Relief Commission.

TUESDAY, APRIL 26TH.

Birth Control Conference.

Mr. POTTER asked the Minister of Health if his sanction had been sought for medical officers of health and their staffs to attend the conference of the National Birth Control Association to be held in London in the near future.—Mr. ERNEST BROWN: My right hon. friend has received and has under consideration an application from one local authority in respect of one of their medical officers.

Cost of Maintenance in Mental Hospitals.

Mr. GORDON MACDONALD asked the Minister of Health the average weekly cost of maintenance of a patient in the county mental hospitals in Lancashire.—Sir E. HILTON YOUNG replied: For the year ended on March 31st, 1931, the average weekly cost of maintenance of a patient in the county mental hospitals in Lancashire was approximately 19*s.* 5*d.*

Cost of Maintenance in Poor-law Institutions.

Mr. GORDON MACDONALD asked the Minister of Health the average weekly cost for the maintenance of an inmate in a public assistance institution in Lancashire.—Sir E. HILTON YOUNG replied: The average weekly cost per inmate, including loan charges, but excluding capital expenditure defrayed from revenue, was, during the year 1930–1931, 21*s.* 6*d.* This cost relates to poor-law institutions only, and not to poor-law hospitals or children's homes.

MEDICAL NEWS

University of London.

At recent examinations the following candidates were successful:—

D.P.M.

With Special Knowledge of Psychiatry.—J. L. Clegg and D. C. Dewar.

A Course on Diseases of the Kidney.

A post-graduate course on Diseases of the Kidney will be held at the Clinique Thérapeutique Médicale de la Pitié, Paris, from May 31st to June 11th, under the direction of Prof. F. Rathery. Particulars may be had from the Secretariat of the Faculty of Medicine of the University of Paris.

Aberdeen University Club, London.

The eighty-seventh half-yearly dinner of this club will be held at the Trocadero Restaurant, at 7 for 7.30 P.M., on Thursday, May 19th, with Sir Arthur Keith, F.R.S., Rector of the University, in the chair. The secretary's address is 9, Addison-gardens, W.14.

Lebanon Hospital for Mental Diseases.

The thirty-third annual meeting of this hospital will be held at Friends House, Euston-road, London, N.W., at 3 P.M. on Wednesday, May 4th. Dr. E. W. G. Masterman, chairman of the hospital, will preside, and the speakers will include Dr. Nathan Raw and Dr. Doris Odlum. The secretary's office is at 55, Wellington-road, N.W. 8.

Demonstrations of Contraceptive Technique.

The Society for Constructive Birth Control and Racial Progress informs us that at 2.30 P.M. on Wednesday, May 4th, demonstrations of contraçeptive technique will be given to practitioners and senior medical students. Application for tickets should be made to the hon. secretary of the society at 108, Whitfield-street, London, W.1.

Society of Chemical Industry.

At the annual meeting of the London section of this society, to be held at Burlington House, Piccadilly, W., at 8 P.M. on Monday, May 2nd, there will be a discussion on Smoke Abatement in Industry.

Royal Sanitary Institute.

Lord Leconfield, Lord-Lieutenant of Sussex, will preside at the forty-third congress of this institute, to be held at Brighton from July 9th to 16th. The preliminary programme, obtainable from the secretary at 90, Buckingham Palace-road, London, S.W. 1, shows that the many subjects of discussion will include the work of local authorities relative to cancer; the prevention of measles mortality; vaccination; birth control; visual fatigue in industry; the medical treatment of the sick poor; mental hygiene; the Town and Country Planning Bill; "slum ending *versus* slum mending"; and the training of nurses, with special reference to the public health services.

Manchester Medical Society.

The annual meeting of this society will be held at 8 P.M. on Wednesday, May 4th. Dr. Garfield Williams, the Dean of Manchester, will give an address on Certain Aspects of Health and Education, with Special Reference to Conditions in Africa and the East.

The Bayliss-Starling Memorial Scholarship.

This scholarship, founded by old students, friends, and admirers, in commemoration of Sir William Bayliss and Prof. E. H. Starling, has an annual value of about £120, with exemption from tuition fees, and is tenable at University College, London. The scholar will be required to follow a course of study approved by the Jodrell professor of physiology, involving a training in the principles of, and methods of research in, physiology and/or biochemistry. Applications must be sent to the Secretary of University College not later than May 14th.

Memorial to Dr. Walter Stevenson.

On April 22nd at Dr. Steevens' Hospital, Dublin, Prof. John Joly, F.R.S., unveiled a memorial tablet erected by his colleagues to the memory of the late Dr. Walter Clegg Stevenson, for many years one of the surgeons to the Hospital. Dr. Stevenson, who died a little over a year ago at the age of 54, was a pioneer in the field of radium therapy, and was responsible, with Prof. Joly, for the method of introducing radon to the tissues contained in hollow needles. The tablet recalls not only his scientific work, but the deep affection felt for Dr. Stevenson by his colleagues.

Donations and Bequests.

The late Mrs. Jane Eadith Catherine Caulfeild's bequests include £2500 for providing a nurse for Froxfield, Hants; £1000 to the British Home and Hospital for Incurables, Streatham; £500 each to the Devonshire Hospital and Buxton Bath Charity, the Petersfield Cottage Hospital, the Royal Institution for Deaf and Dumb, Derby, the Samaritan Free Hospital for Women, the Royal Blind Pension Society; £250 each to St. Mary's Home for Poor Children, Broadstairs; the St. Mary's Hospital for Women and Children, Plaistow; the Hospital for Consumption and Diseases of the Chest; the East London Hospital for Children and Dispensary for Women; the Royal Hants County Hospital; the Royal Sea Bathing Hospital, Margate; and the Lord Mayor Treloar's Cripples' Hospital and College, Alton.—The late Colonel Warden Robertson Maxwell left among other bequests, £4000 to the Royal Hospital for Sick Children, Glasgow; £1000 each to the Glasgow Royal Cancer Hospital, Glasgow Royal Hospital, Glasgow Western Hospital, and Glasgow Victoria Infirmary.—Mr. and Mrs. Charles Phibbs, of Llanbedr, Merionethshire, have given £2000 to endow two beds for Merionethshire Voluntary Orthopædic Association patients in the Shropshire Orthopædic Hospital.

Students' Carnival Beds.

Last week the Lord Mayor of Birmingham unveiled at the Queen's Hospital two beds which have been endowed with the proceeds of the Birmingham students' carnival last year. Sixteen beds have now been endowed from this source.

Royal National Orthopædic Hospital.

At the annual meeting last week it was reported that in 1931 income on general account exceeded expenditure by over £5000; on that account £72,000 had been collected in addition to donations amounting to £9000 in reduction of the building debt. Both in-patients and out-patients exceeded all previous numbers. Clinics are being established in coöperation with local authorities where patients can be examined and out-patient treatment given throughout London and the home counties and even in Wales. Evening clinics are also being established in Gt. Portland-street for patients who are unable to attend the hospital during ordinary hours.

National Association for the Prevention of Tuberculosis.

This association will hold its eighteenth annual meeting in London—in the Great Hall of University College, Gordon-street, W.C.—from July 21st to 23rd. After the opening by Sir Hilton Young, the Minister of Health, the first day will be devoted to addresses on the Influence of the Discovery of the Tubercle Bacillus on Medicine (Dr. R. A. Young), Surgery (Sir Henry Gauvain), and Public Health (Dr. W. C. White, of Washington, D.C.). Later Dr. F. J. H. Coutts will open a discussion on the Protection from Tuberculosis of the Young Adult. On the second day the subject before the conference will be the Need for Continuity of Care in Tuberculosis, the principal speakers being Miss Edith McGaw and Dr. Septimus Walker, hon. secretary and tuberculosis officer respectively of the Paddington Tuberculosis Dispensary. The third day, Saturday, will be devoted to visits to Queen Mary's Hospital for Children, Carshalton, and the National Institute for Research in Dairying, Reading.

County Hospital Accommodation in Durham.

Dr. Charles Franks, medical officer of health for the county of Durham, has submitted to the county council a scheme for the reorganisation of hospital accommodation. It is recommended that the number of isolation hospitals should be reduced from 28 to 12 where, in each instance, there is ample room for extension. Dr. Franks points out that with the present accommodation of 700 beds the total number of patients admitted during 1930 was 3213 which, assuming the average stay of each patient to be 30 days, means that of the 365 days of the year the beds were only occupied on 138 days, or that the hospital accommodation was only used for approximately five months of the year. In the scheme of reorganisation the number of beds would be reduced from 700 to 582. These beds, based on the figures of last year, would still leave a sufficiently large margin to deal with any moderate epidemic. He also proposes to reduce the existing number of ten small-pox hospitals to three, which would decrease the number of beds available from 212 to 83. The scheme admittedly may require revision in view of a newly proposed readjustment of the boundaries of county areas. Meanwhile, some of the local authorities are opposing it.

Fellowship of Medicine and Post-Graduate Medical Association.

An afternoon course in diseases of the skin will be held at St. John's Hospital, Leicester-square, London, from May 2nd to 28th. An evening course in physical medicine will be given at the London Light and Electrical Clinic, Ranelagh-road, from 8 to 9 P.M., on Mondays and Wednesdays from May 2nd to 25th. A week-end course in clinical surgery, consisting of demonstrations on cases, is to be held at the Royal Albert Dock Hospital on Saturday and Sunday, May 7th and 8th, from 9.30 A.M. to 6.15 P.M. daily. This course is specially suitable for candidates for the F.R.C.S., but is also intended for general practitioners. A lecture-demonstration on Rheumatic Infection and Heart Disease in Children will be given from 10.30 A.M. to 12 noon by Dr. Bernard Schlesinger at the Children's Heart Hospital, West Wickham, on Saturday, May 7th. (Application for this should be made to the Fellowship not later than May 3rd.) A course of three epidiascope and laboratory demonstrations will be given by Dr. Knyvett Gordon at 10, Bedford-square, at 8.30 on Wednesdays, May 18th, 25th, and June 1st. Though not restricted to candidates for the M.R.C.P., these demonstrations are intended to be useful to them. Further particulars of all courses may be had from the secretary of the Fellowship, 1, Wimpole-street, W. 1.

Optical Society.

This society has decided to amalgamate with the Physical Society of London, and steps are being taken accordingly.

Contributory Schemes.
